JUDICIAL COUNCIL

Edward R. Cunniffe. Chairman,	New York, 1954
Louis A. Buie	Rochester, Minn., 1955
Walter F. Donaldson	Pittsburgh, 1956
H. L. Pearson Jr.	Miami, Fla., 1957
G. A. Woodhouse	Pleasant Hill, Ohio, 1958
George F. Lull, Secretary	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

W. L. Pressly	Due West, S. C., 1954
C. T. Stone Sr.	Galveston, Texas, 1954
Harvey B. Stone	Baltimore, 1955
J. M. Faulkner	Boston, 1955
Guy A. Caldwell	New Orleans, 1956
John W. Cline	San Francisco, 1956
F. D. Murphy	Lawrence, Kan., 1957
H. G. Weiskotten, Chairman,	Skaneateles, N. Y., 1957
Victor Johnson	Rochester, Minn., 1958
L. S. McKittrick	Boston, 1958
Edward L. Turner, Secretary	Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

Stanley P. Reimann	Philadelphia, 1954
Alphonse McMahon	St. Louis, 1954
Carl A. Lincke	Carrollton, Ohio, 1955
Michael E. DeBakey	Houston, Texas, 1956
Samuel P. Newman	Denver, 1957
Henry R. Viets, Chairman	Boston, 1958
Charles H. Phifer	Chicago, 1958
Walter B. Martin ex officio	Norfolk, Va.

COUNCIL ON MEDICAL SERVICE

Joseph D. McCarthy	Omaha, 1954
H. B. Mulholland	Charlottesville, Va., 1955
C. E. Wertz	Buffalo, 1956
Elmer Hess, Chairman	Erie, Pa., 1957
L. M. Orr II	Orlando, Fla., 1958
R. B. Homan Jr.	El Paso, Texas, 1958
Edward J. McCormick	Toledo, Ohio
Louis H. Bauer	Hempstead, N. Y.
David B. Allman	Atlantic City, N. J.
Mr. Thomas A. Hendricks, Secretary	Chicago

COUNCIL ON CONSTITUTION AND BYLAWS

Floyd S. Winslow	Rochester, N. Y., 1954
B. E. Pickett Sr.	Carrizo Springs, Texas, 1955
L. A. Buie, Chairman	Rochester, Minn., 1956
James Stevenson	Tulsa, Okla., 1957
Stanley H. Osborn	Hartford, Conn., 1958
E. S. Hamilton	Kankakee, Ill.
Edward J. McCormick	Toledo, Ohio
James R. Reuling	Bayside, N. Y.
E. Vincent Askey	Los Angeles

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

W. C. Cutting	San Francisco, 1953
Keith S. Grimson	Durham, N. C., 1953
Morris Fishbein	Chicago, 1953
M. H. Seevers	Ann Arbor, Mich., 1953
Joseph Stokes Jr.	Philadelphia, 1954
Perrin H. Long	Brooklyn, 1954
W. G. Workman	Bethesda, Md., 1954
J. Bordley III	Cooperstown, N. Y., 1954
Carl A. Dragstedt	Chicago, 1955
Isaac Starr	Philadelphia, 1955
Joseph Hayman	Boston, 1955
E. M. K. Geiling	Chicago, 1956
Elmer M. Nelson	Washington, D. C., 1956
Henry K. Beecher	Boston, 1956
Torald Sollmann, Chairman	Cleveland, 1957
James P. Leake	San Jose, Calif., 1957
C. Guy Lane	Boston, 1957
Robert T. Stormont, Secretary	Chicago

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

(Standing Committee of Board of Trustees)

M. A. Bowie	Swarthmore, Pa., 1953
Arthur L. Watkins	Boston, 1953
W. J. Zeiter	Cleveland, 1953
F. H. Krusen, Chairman,	Rochester, Minn., 1954
Anthony C. Cipollaro	New York, 1954
Felix Butte	Dallas, Texas, 1954
O. Glasser	Cleveland, 1955
Shields Warren	Boston, 1955
Derrick Vail	Chicago, 1955
Frank R. Ober	Boston, 1956
D. M. Lierle	Iowa City, 1956
W. W. Coblentz	Washington, D. C., 1957
George M. Piersol	Philadelphia, 1957
Ralph E. DeForest, Secretary	Chicago

COUNCIL ON FOODS AND NUTRITION

(Standing Committee of Board of Trustees)

William J. Darby	Nashville, Tenn., 1953
C. A. Elvehjem	Madison, Wis., 1953
John B. Youmans	Nashville, Tenn., 1953
L. A. Maynard	New York, 1954
Grace Goldsmith	New Orleans, 1954
Charles S. Davidson, Chairman	Boston, 1954
Clement A. Smith	Boston, 1955
C. S. Ladd	Washington, D. C., 1955
Howard B. Lewis	Ann Arbor, Mich., 1956
George R. Cowgill	New Haven, Conn., 1956
W. H. Griffith	Los Angeles, 1957
James R. Wilson, Secretary	Chicago

COUNCIL ON INDUSTRIAL HEALTH

(Standing Committee of Board of Trustees)

R. T. Johnstone	Los Angeles, 1953
A. J. Lanza, Chairman	New York, 1953
C. D. Selby	Port Huron, Mich., 1953
Warren F. Draper	Washington, D. C., 1954
Henry H. Kessler	Newark, N. J., 1954
Oscar A. Sander	Milwaukee, 1954
Lloyd E. Hamlin	Chicago, 1955
Robert A. Kehoe	Cincinnati, 1955
W. P. Shepard	New York, 1956
M. N. Newquist	New York, 1956
James S. Simmons	Boston, 1957
J. H. Sterner	Rochester, N. Y., 1957
C. M. Peterson, Secretary	Chicago

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

(Standing Committee of Board of Trustees)

Roscoe L. Sensenich	South Bend, Ind., 1953
Harold C. Lueth	Evanston, Ill., 1953
Harold S. Diehl	Minneapolis, 1954
Richard L. Meiling	Columbus, Ohio, 1954
A. A. Brindley	Toledo, Ohio, 1955
W. J. Baker	Chicago, 1955
Stafford L. Warren	Los Angeles, 1956
Herbert B. Wright	Cleveland, 1956
James C. Sargent, Chairman	Milwaukee, 1957
Perrin H. Long	Brooklyn, 1957
Mr. C. Joseph Stetler, Secretary	Chicago

COUNCIL ON RURAL HEALTH

(Standing Committee of Board of Trustees)

F. S. Crockett, Chairman	Lafayette, Ind., 1953
G. F. Bond	Bat Cave, N. C., 1953
C. S. Mundy	Toledo, Ohio, 1954
C. R. Henry	Little Rock, Ark., 1954
F. A. Humphrey	Ft. Collins, Colo., 1955
N. H. Gardner	E. Hampton, Conn., 1955
A. T. Stewart	Lubbock, Texas, 1956
J. F. Doughty	Tracy, Calif., 1956
W. J. Weese	Ontario, Ore., 1957
W. A. Wright	Williston, N. D., 1957
Mrs. A. Hibbard, Secretary	Chicago

COMMITTEE ON MENTAL HEALTH

(Standing Committee of Board of Trustees)

W. H. Baer	Peoria, Ill., 1953
L. H. Bartemeier, Chairman	Detroit, 1953
L. H. Smith	Philadelphia, 1954
Maurice Levine	Cincinnati, 1954
F. M. Forster	Washington, D. C., 1955
H. T. Carmichael	Chicago, 1956
M. R. Kaufman	New York, 1957
R. J. Plunkett, Secretary	Chicago

The Secretary, Assistant Secretary and Editor are ex officio members of all Standing Committees

SECTION OFFICERS 1953-1954

Anesthesiology—Chairman, Moses H. Krakow, Bronx 53, N. Y.; Secretary, John S. Lundy, 102 Second Ave. S.W., Rochester, Minn.

Dermatology and Syphilology—Chairman, George M. Lewis, New York 21; Secretary, J. Walter Wilson, 3875 Wilshire Blvd., Los Angeles 5.

Diseases of the Chest—Chairman, Jay Arthur Myers, Minneapolis 2; Secretary, John F. Briggs, 350 St. Peter St., St. Paul 2.

Experimental Medicine and Therapeutics—Chairman, Irvine H. Page, Cleveland 6; Secretary, George E. Burch, 1430 Tulane Ave., New Orleans 12.

Gastroenterology and Proctology—Chairman, Donovan C. Browne, New Orleans 15; Secretary, Everett D. Kiefer, 605 Commonwealth Ave., Boston 15.

General Practice—Chairman, Frederic Ewens, Manhattan Beach, Calif.; Secretary, E. I. Baumgartner, 25 Alder St., Oakland, Md.

Internal Medicine—Chairman, Herrman L. Blumgart, Boston 15; Secretary, A. Carlton Ernstene, 2020 E. 93d St., Cleveland 6.

Laryngology, Otology and Rhinology—Chairman, Sam H. Sanders, Memphis 3, Tenn.; Secretary, Hugh A. Kuhn, 112 Rimbach St., Hammond, Ind.

Military Medicine—Chairman, Maj. Gen. Harry G. Armstrong (MC) USAF, Washington, D. C.; Secretary, Col. Charles L. Leedham (MC) USA, Office of the Surgeon General, Department of the Army, Washington 25, D. C.

Nervous and Mental Diseases—Chairman, A. Earl Walker, Baltimore 5; Secretary, Karl O. Von Hagen, 2010 Wilshire Blvd., Los Angeles 57.

Obstetrics and Gynecology—Chairman, Bernard J. Hanley, Los Angeles 57; Secretary, D. Frank Kaltreider, University Hospital, Baltimore 1.

Ophthalmology—Chairman, Trygve Gundersen, Boston 15; Secretary, Harold G. Scheie, 313 S. 17th St., Philadelphia 3.

Orthopedic Surgery—Chairman, Charles N. Pease, Chicago 3; Secretary, Frederick R. Thompson, 16 E. 90th St., New York 28.

Pathology and Physiology—Chairman, J. Earl Thomas, Philadelphia Secretary, Edwin F. Hirsch, 1439 S. Michigan Blvd., Chicago 5.

Pediatrics—Chairman, Oliver L. Stringfield, Stamford, Conn.; Secretary, Wyman C. C. Cole, 3001 W. Grand Blvd., Detroit 2.

Physical Medicine and Rehabilitation—Chairman, Walter M. Solomon Cleveland 15; Secretary, Walter J. Zeiter, 2020 E. 93d St., Cleveland 6.

Preventive and Industrial Medicine and Public Health—Chairman, Jear S. Felton, Oklahoma City 4; Secretary, Frank Princi, University of Cincinnati, College of Medicine, Cincinnati 19.

Radiology—Chairman, Kenneth D. A. Allen, Denver 2; Secretary, Tralar Leucutia, Harper Hospital, Detroit 1.

Surgery, General and Abdominal—Chairman, Emile F. Holman, San Francisco 15; Secretary, Walter G. Maddock, 250 E. Superior St., Chicago 11.

Urology—Chairman, Rex E. Van Duzen, Dallas 1, Texas; Secretary Rubin H. Flocks, University Hospitals, Iowa City.

COURSE AND PROGNOSIS OF ESSENTIAL HYPERTENSION

FOLLOW-UP OF 453 PATIENTS TEN YEARS AFTER ORIGINAL SERIES WAS CLOSED

Robert Sterling Palmer, M.D.
and
Hugo Muench, M.D., Boston

This paper summarizes the present status of a series of patients in whom essential hypertension was diagnosed from 10 to 12 or more years ago; no new patients have been added in the last 10 years. Two previous reports have been made on this series; one four years ago[1] and one six years ago.[2] Classification was originally made according to criteria previously outlined.[2] In brief, grade 1 included persons with minimal organic change, or none, as recognized by ordinary clinical examination in the three vital areas, head, heart, or kidneys; grade 2, those with definite or marked change, but no functional impairment; grade 3, those with organic change with functional impairment; and grade 4, those with papilledema. Classification was made according to maximum change found in any one or more areas without regard to elevation of blood pressure. A few patients were seen as long as 20 years ago; the majority, however, came under observation between 1935 and 1940. Ten years is the shortest observation period except for those who died. Over a thousand patients were originally seen, but over 40% were excluded because they were seen only once or were observed too briefly, because classification was doubtful, because the diagnosis was glomerulonephritis or transient nervous hypertension, or, finally, because sympathectomy was performed. Six hundred forty-six persons were included in the original classifications.

Treatment was chiefly dietary (fat-excluded, low calory, or salt poor, or both; occasionally strict low sodium) together with mild sedation and sometimes potassium sulfocyanate. More recently, a few patients were maintained on the rice diet and some were given veratrum preparations. In general, treatment was according to conventional indications, the ordinary rules of good hygiene, and simple psychotherapy varied and adapted to the particular patient.[3] These patients are considered valid controls for comparison with the results of surgical treatment or with those of any single medical treatment consistently followed.

Figure 1[1] shows the percentage of survivors at each check period. The dotted line indicates a rough graphical prediction, made after 8 years of treatment, of the per cent of survival expected at the end of 10 to 12 years. Observed survival was better than expected in each of the grades: grade 1, 58% expected, 64% observed; grade 2, 24% expected, 42% observed; grade 3, 2% expected, 11% observed; and grade 4, none expected, 4% observed. This indicates that there has been a general tendency for mortalities to decrease in later years.

It is obvious that there are definite differences in the observed mortalities of different grades and that there is considerable validity in the criteria on which the distinctions of grading rest. The duration of disease in living patients is much the same for all groups; it is determined chiefly by the fact that the patients have survived at least 10 years since the series was closed. The average duration in patients who died, measured from original inclusion in the study, varies greatly between grades, as does the proportion of original patients followed to the present: grade 1, 5.9 years' duration, 53% followed; grade 2, 4.4 years' duration, 62% followed; grade 3, 3.3 years' duration, 85% followed; and grade 4, one year duration, 95% followed. It is evident that success in follow-up increases with shorter average survival of dead patients. This is to be expected, since the combination of high mortality and early death allows less chance for loss from observation.

Death certificates of deceased patients and reports from attending physicians and from members of the family included, predominantly, factors associated with

hypertension as cause of death. This is not surprising, since the existence of hypertension was generally known to the person furnishing the information. The proportion of causes assigned to major groups under each grade are listed in table 1.

The original follow-up study made on our group of patients is inherently a life table study, and the curves in figure 1 are essentially curves of survival of four subgroups of patients starting with 100% of each subgroup admitted to the study in the beginning. The curves have considerable validity as they stand, in view of the fact that few or no patients were admitted to each subgroup after the first few years and none at all were added during the last 10. The study is not, therefore, greatly biased by having an excess of observations in the early years of experience. On the other hand, subgroups are not homogeneous as to age and sex or as to periods of observation, factors that may affect the results of the analysis. An additional study of the data has, therefore, been made on a life table basis in order to remove possible bias and to discover additional differences that might exist.

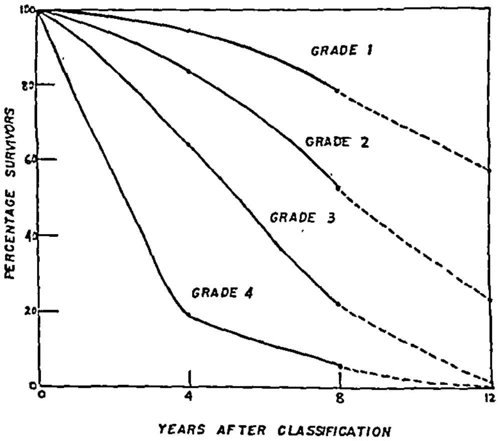

Fig. 1.—Percentage of survivors of each grade observed 4 and 8 years after classification (solid line) and estimated expected percentage of survivors at 12 years (broken line).

All studies of this kind suffer from the serious fault of incomplete follow-up. It must be assumed that the portion of the group lost from observation might be heavily weighted with patients who died, in which case the true mortality figures would be greater than those obtained from the remainder. On the other hand, if the lost group consisted mainly of patients who improved and, therefore, drifted away from treatment, the error would be in the opposite direction. Which error, if either, has occurred in this study is unknown. We feel that the exceptionally careful follow-up that preceded this study was more likely to turn up previously undiscovered death records than living patients who had disappeared. The fact that follow-up is more nearly complete in groups with highest mortalities lends additional strength to the assumption that actual mortalities are, if anything, somewhat less than those obtained from the data.

The first analysis was a study of person years (table 2).[4] It is based on the fact that there will be some deaths in any general population group followed over a period of time. The criterion of risk of a special group is then the ratio of its observed deaths, year by year, to the number of deaths that would have been expected in a group of the normal population made up in exactly the same way as to age, sex, and race. Expected deaths are easily calculated from life tables, and for this purpose we used the "United States 1939 to 1941" tables [5] for white men and women, respectively. The ratios obtained are abstracted in table 2.

TABLE 1.—*Causes of Death Listed for Patients with Hypertension*

	Cerebral, %	Heart, %	Kidney, %	Total, %	Unknown, %
Grade 1	40	35	2.5	77.5	5
Grade 2	33	33	10	76	15
Grade 3	34	46	11	91	3
Grade 4	23	29	40	92	4

Certain general conclusions may be drawn from these data. (*a*) Relative risk is highest in younger persons and decreases rapidly with age. Older women with milder grades seem certainly to be no worse off, as regards mortality, than the general population. (*b*) Women have definitely lower mortalities than do men, except for those in grade 4. Women in the first three grades tend to be somewhat older than men. The proportion of women decreases markedly from grade 1 to grade 4. It may be said that women appear to have a milder type of hypertension than men do and a slower rate of progression that leads to a higher mean age for women in each of the first three grades, especially when duration is taken into account. (*c*) Average age increases from grade 1 to grade 3 and indicates that, to some extent, each grade is a successive stage of the preceding one. There is, on the other hand, considerable evidence of a tendency for persons to remain in the grade in which classification was originally made. This would imply that there is considerable variation in the original characteristics of hypertension and that different degrees of severity tend to exist from the beginning. Certainly at least some of the 36% of grade 1 patients who died, as well as some of the 58%

TABLE 2.—*Ratio of Observed to Expected Deaths By Person Years*

[5] United States Department of Commerce, Bureau of the Census: Sixteenth Census of the United States: 1940, United States Life Tables and Actuarial Tables, 1939-1941, by Thomas N. E. Greville, prepared under the supervision of Halbert L. Dunn, Washington, D. C., United States Government Printing Office, 1946.

of grade 2 must have advanced to severer types. Relative excesses of mortality decrease greatly, however, with advancing years, and the progression to severer types must be slow at higher ages. (*d*) Grade 4 presents a picture all its own. The patients tend to be affected earlier in life, and their hypertension tends to run a highly acute and lethal course.

TABLE 3.—*Death Rate Per 1,000 Person Years by Age and Duration of Disease*

Grade	1		2		3		4	
Duration, years	−5	5+	−5	5+	−5	5+	−1	1+
Age								
0-34	38	..	235	..	667	182	1000	429
35-54	23	44	59	57	289	279	584	791
55-74	53	31	111	76	167	174	1000	1333
75 and over	85	110	167	32	183	170	....	...
Total	39	39	93	65	216	199	730	701
Person years	567	461	280	382	436	426	34	38
Deaths observed	22	18	26	25	91	85	25	27

The age categories of table 2 reflect increased duration as well as advancing age. The decreasing relative mortalities could, therefore, be connected with either age or duration, or both. In order to determine the important factor, a second tabulation was made and is abstracted in table 3.[4] In this table, sexes have been combined, but figures by age are split into two groups on the basis of duration of disease at time of entry into the study. In order to obtain groups of roughly similar size, the division was made at five years' duration for the first three grades and at one year for the fourth. It is somewhat surprising to find no consistent differences associated with duration of disease, with the single exception of the youngest patients in grade 4. In those, duration of less than a year is definitely associated with higher mortality.

It is true that duration rests on patients' statements and is, therefore, not clearly defined. There must be definite differences, however, in average duration between each two comparison groups; it is surprising not to find them connected with differences in observed mortality. It can only be concluded that mortality in hypertension varies greatly with age, but little with previous duration of disease at a given age.

TABLE 4.—*Ratio of Observed Survivors to Those Expected from Life Table (l_x)*

Years of Classification	Grade 1	Grade 2	Grade 3	Grade 4
0.5	0.998	0.962	0.885	0.502
2.5	0.960	0.889	0.549	0.094
4.5	0.941	0.704	0.393	0.076
6.5	0.896	0.661	0.336	0.054
8.5	0.831	0.592	0.266	0.055
10.5	0.798	0.589	0.180	0.037
12.5	0.815	0.566	0.162	

We tried another type of analysis, suggested by Berkson and Gage,[6] on these data. It is based on the proportion of each group originally classified by grade surviving year by year after inclusion in the study, and the result is, therefore, similar to the direct survival curves in figure 1. Survival is influenced, however, not only by the disease in question but by other forces of mortality connected with age and sex. Grade 3 patients, for example, would be expected to die at a faster rate than those in grade 1; differences in hypertension were disregarded merely because the groups were more heavily weighted with older men. In order to equalize such differences, observed survival is compared with the proportion surviving in groups made up of persons of the same age and sex drawn from the general population. United States life tables were used as the source of comparison groups.

The results of the analysis are abstracted in table 4[4] and are graphed in figure 2. The curves are similar to those in figure 1, but they now refer, not to actual survivors, but to the ratio of survivors observed to those expected to survive in the general population. A horizontal line, therefore, does not mean absence of deaths but mortality at rates expected in a normal population. It can be seen that, in each group, patients die faster than expected and that this difference rapidly increases with grade. On the other hand, in each grade, the relative decrease slows markedly with the passage of years after inclusion in the study. Since the effects of increasing age and duration of hypertension are combined in this table it is impossible to determine the relative influence of each, but the previous analysis indicates that age is the more important factor. The simple shape and apparent homogeneity of the relative survival curves naturally lead to attempts to explain them on a basis of simple mathematical rationalization.

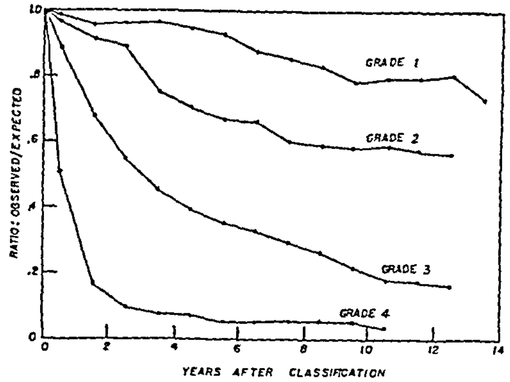

Fig. 2.—Ratio of observed survivals in each grade to expected (l_x) by annual intervals beginning six months after classification.

There are at least three hypotheses that may be applied to the analysis of the survival ratio curves. (*a*) There is a continous rate of decrease of survivors below expected. This seems to be the case in grade 1, in which some 20 per 1,000 survivors are lost each year, in addition to deaths normally expected. This would be a relatively large increase in young ages, but relatively a much smaller number as age advances. (*b*) There is a "cured" component that follows expected mortality rates, plus a remainder dying at a continuous, increased ratio. Berkson and Gage found that this described their data on postoperative cancer survival very well. Here grade 4 seems well described by this assumption; it is, however,

---

6. Berkson, J., and Gage, R. P.: Survival Curves for Cancer P-t' Following Treatment, J. Am. Statistical A. 47: 501-515 (Sept.) 1952.

much the smallest group, and no definite conclusions can be drawn. (*c*) Excess mortality itself follows a curve that starts high but continually decreases. A priori, this would seem to be the most logical assumption for a disease of this type. It actually furnishes the best description of the curve for grade 3, while either this one or the previous assumption (*b*) equally well describes observations on patients in grade 2.

There is little profit in arguing differences in assumptions or in their results as based on a limited series of cases. However, the statistical note that follows gives constants of the respective curves for each grade. The resulting curves under different assumptions are closely similar and can be used for the purpose of predicting survival in each grade for groups of patients under conservative treatment.

STATISTICAL NOTE

(*a*) Assumption of constant loss: $dy/dt = -by$ so $y = e^{-bt}$

Grade 1: $b = 0.0206$

(*b*) Assumption of normal group plus constant loss in remainder:

$$dy/dt = -b(y - a) \text{ so } y = a + (1 - a)e^{-bt}$$

	a	b

COMMENT

A number of questions are raised by this study. Are the good results in certain types of treatment determined largely by the selection of patients from grades of disease in which the prognosis is good in any case? Is the disease in persons with the best prognosis (such as those in grade 1) primarily neurogenic or functional, and does it tend to remain in the same grade without developing organic lesions, while excess mortality is due to hypertension that is primarily organic and that moves on to more serious conditions? Are mortality rates in grades 3 and 4 so high that treatment, in itself hazardous and uncomfortable, may be justified in an effort to prolong life? Is on the other hand, the use of potentially dangerous hypotensive agents indicated in milder degrees of hypertension in which the natural survival time is so long? Definitive answers to such questions must come from carefully controlled studies of survival in adequate numbers of patients treated by various methods.

SUMMARY AND CONCLUSIONS

This is a report on the survival of 453 patients with different degrees of essential hypertension who were first seen and classified by one of us (R. S. P.) more than 10 years ago and who were recently subjected to intensive follow-up. The essential validity of separation of cases into four grades according to clinical criteria has been established by this analysis as well as by two previous ones. The patients included may be regarded as a reasonably unbiased sample of the 10 or 15 million Americans suffering from hypertension, and the results of the analysis may be accepted as a base line for the results of conservative medical treatment with which other treatment results may be compared. Because of the inevitable loss of patients from observation, it is felt that mortality rates as given here may be somewhat exaggerated.

Several tentative conclusions may be made. 1. Relative risk is highest in young ages and decreases rapidly with age. 2. Mortality in women is definitely lower (except for those in grade 4), and increase of severity is slower. At higher ages in the milder grades, the mortality of women compares favorably with that of the general population. 3. Average age increases from grade 1 to grade 3. Each higher grade must, to some extent, be a later development of the previous one. 4. Duration of disease, apart from advancing age, does not seem to have any effect on mortality, except in grade 4 in which short duration is associated with higher mortality at youngest ages. 5. Survival rates relative to those of the general population follow simple patterns that may be expressed in basic mathematical terms. In this way, a basic expectation of survival may be established for any grade of disease, furnishing a base for comparison with the results of other methods of treatment. 6. With each increase in grade, patients die at a faster rate than that expected. In general, this increase in mortality tends to diminish with time under observation or higher ages.

Misdirective Counseling.—There are counseling visionaries and counseling realists. . . . One can correctly appraise a client's limitations as well as his abilities, interests, and aptitudes, can correctly interpret the job market, and yet participate with the client in making a crucial counseling mistake: the mistake of failing to take a penetrating view of the client's level of motivation. When a counselor looks back over his "great rehabilitations," he cannot but be impressed with the determination and will-to-succeed that distinguished each of them. Nor were these unusual or highly imaginative counseling cases of the 100-to-1-shot variety. Most probably they were ordinary programs involving the provision of some special training or special equipment, and leading toward an immediate and obtainable goal. What made these cases so startling was that after the first goal was reached the client went on and on under his own power. . . . But conversely, when the counselor looks back on so many of the other kinds of cases—the clients on whom was lavished so much of money, time, and attention, only to have them drop out or return to public assistance—then he is struck with the absence of a constructive motivation. Motivation is not to be confused with wish for status, or yearning. Motivation implies an overpowering will to do; it is action, not fantasy. Yet *all* too often the daydreams of the unable are treated by the more visionary of counselors as though these were mature interests, clamoring for release. . . . Not all individuals with I.Q. of 140 want to go to college; some of them are content to pump gas in a filling station and will expend no energy to go beyond that. It would be poor counseling to match the potential talent to the maximal job if the individual habitually operates on a lesser level. There is nothing terribly abnormal about squandering or wasting one's talent. . . . The wise counselor is not one who moralizes on what a client should do with his talents (and proceeds to build a plan around it); rather he seeks to determine what the client will do, and then assists him in a maximal adjustment thereto.—R. A. Peckham, Misdirective Counseling, *Journal of Rehabilitation,* May-June, 1953.

CLINICAL USE OF HYDRALAZINE AND HEXAMETHONIUM IN TREATMENT OF HYPERTENSION

Robert R. J. Hilker, M.D., Paul S. Rhoads, M.D.
and
Carl E. Billings, M.D., Chicago

It is our purpose to report the use of hydralazine (Apresoline) hydrochloride and hexamethonium (Bistrium) in clinical practice. Evaluation of side-effects, safety, best method of administration, and clinical response are stressed. Excellent papers also discussing the use of these drugs have been published during the last year.[1]

It was proved that all patients included in our series had hypertension. All had average blood pressures of 150/100 mm. Hg or more prior to therapy except one. This 26-year-old patient had a progressively rising pressure following acute glomerulonephritis and had a pretreatment average blood pressure of 150/96 mm. Hg. The maximum pressure was 300/180 mm. Hg. The majority of patients were from the practice of two of us. The rest were from the practices of other physicians on the staff of Wesley Memorial Hospital. Patients' ages ranged from 17 to 71 years. A few of the patients were entirely free of symptoms. The majority had one or more of the usual symptoms of hypertensive cardiovascular disease. Some originally were completely incapacitated and bedfast.

A thorough investigation to determine the cause of hypertension was conducted in all patients. The following laboratory data were obtained: chest roentgenogram, intravenous pyelogram, electrocardiogram, basal metabolic rate, routine urinalysis and hematological examination, urine culture, urine concentration test, urea clearance test, phenylsulfonphthalein excretion, benzodioxane or regitine test, amobarbital sodium test, serum nonprotein nitrogen, serum creatinine, fasting blood sugar, and sedimentation rate. A presumed cause of hypertension was found in only five: two had a history of acute glomerulonephritis without definite proof of residual renal involvement; one had polycystic kidneys; one had persistent hypertension following a severe toxemia of pregnancy; and one had intercapillary glomerulosclerosis. In addition, four patients were in the terminal phase of malignant hypertension.

In evaluation of therapeutic results, blood pressure readings were taken as follows. Previously recorded pressures, in most cases extending over several years, were averaged and used as the pretreatment level. All patients were ambulatory and carried on their usual activities except those with malignant hypertension; these were hospitalized part of the time. Pressure readings during therapy were taken in the office. At each visit, three to five readings were taken, and the figure for that day was recorded as the average. Pressures reported as therapeutic results are averages of those recorded on the last three consecutive visits. All pressures during therapy were taken by the same observer.

Diets included from one gram of sodium to as much as desired. Restricted sodium diets were used to treat or prevent edema from cardiac decompensation.

THERAPY WITH HYDRALAZINE

Pharmacology.—It is not within the scope of this paper to discuss completely the pharmacology of hydralazine hydrochloride. Its actions are not yet completely known, but its major actions are reported to be sedation of the vasopressor center,[2] blocking a hypertensive hormone,[3] increasing renal blood flow,[4] increasing cardiac output,[4] pooling blood selectively in the splanchnic system,[4] and partially blocking adrenergic impulses.[2b]

Side-Effects.—Side-effects observed in 100 patients over a period of 17 months (the average was 8 months per patient) included headache in 39; nausea, 20; tachycardia, 16; flushed face, 12; nasal congestion, 11; pitting edema of ankles, 9; periorbital edema, 7; vomiting, 7; insomnia, 7; dizziness, 6; fever (associated with 22% eosinophilia in 1), 4; chills, 4; myalgia, 3; overstimulation, 3; tightness of face, 2; blurred vision, 2; watery eyes, 2; postural hypotension, 2; anginal attack, 1; burning in chest, 1; and drowsiness, 1. Of these 100 patients, 50 are reported in the evaluation of hydralazine therapy, 14 are reported in the evaluation of combined therapy, 12 were unable to tolerate the drug, and 24 were either lost to the series or observed for too short a time to be included in therapeutic results.

It was necessary to discontinue therapy in 12 patients because of severe toxic reactions, such as headache, nausea and vomiting, fever, pitting edema of the ankles,

and, in one case, an anginal attack. There was no effective treatment for any of these severe reactions. In the other patients experiencing reactions, the majority of symptoms disappeared spontaneously in about two weeks. Antihistaminic drugs, and in severe cases phenobarbital in addition, relieved headaches, nasal congestion, watery eyes, and periorbital edema.

The pitting edema of the ankles was generally accompanied by macular erythema covering the ankles only. It did not respond to a low salt diet, diuretics, or antihistaminic drugs. Side-effects were minimized when therapy was started with small doses and the doses were increased very gradually. Perhaps the incidence of side-effects in this series is higher than will be reported in the future because the importance of dosage was not appreciated early in the study. No evidence of chronic toxicity was observed.

Administration of Hydralazine.—This study was confined to oral administration. Initially, doses were given five times daily; later, doses were given four times daily. The latter proved equally effective and more convenient. Whether the drug was taken before or after meals made little difference. A satisfactory method of administration must do two things, minimize side-effects and lower pressure only gradually. The following system met these requirements. The first day a 25 mg. tablet was given with breakfast and the evening meal. Thereafter the total dose was increased 25 mg. a day. A schedule of doses was prepared for each patient (table 1).

TABLE 1.—*Dosage Schedule for Milligrams of Hydralazine*

* 25 mg. tablets are blue.
† 50 mg. tablets are red.

In a period of seven days the total daily dose was increased from 50 to 200 mg. If severe side-effects occurred, the dose was held stationary for a time and then increased more gradually. The dose was also held stationary whenever a satisfactory pressure drop was obtained. Therapy may also be started with 10 mg. doses and increased in a similar manner.

The range of daily doses that were effective in producing a significant fall in pressure (21 mm. Hg or more in systolic or diastolic pressure) were 100 mg. effective in three patients; 125 mg., two; 150 mg., one; 200 mg., four; 250 mg., eight; 300 and 375 mg., four patients each; 500 mg., seven; and 625 and 750 mg., one patient each. There was marked individual variation making careful gradation of the dose more imperative. The maximum dose given was 900 mg.; this was completely ineffective in three patients. It was felt that doses in excess of 900 mg. daily were not indicated. No subnormal pressures were observed regardless of the dose.

No case of true tolerance to hydralazine was noted. Often it was necessary to increase the dose from time to time, but no patient with an initial favorable response became refractory to treatment. Several patients voluntarily stopped therapy. When therapy was again started, they responded to smaller doses. In some cases, it was possible to reduce the dose and to maintain the same therapeutic results.

* Pressures all recorded in recumbent position; no postural drop noted during hydralazine therapy.

Results of Therapy with Hydralazine.—Fifty patients were treated for periods varying from 1 to 17 months; the average was 8 months. The results obtained in lowering blood pressure are summarized in table 2.

A sustained fall in either systolic or diastolic pressure of more than 20 mm. Hg is arbitrarily considered significant. The actual significance of any drop in pressure depends on the initial level and the symptomatic response. It is felt, however, that this standard represents a true therapeutic response.

The systolic and diastolic responses in individual patients are correlated in table 3. These results indicate that long-term therapy with hydralazine hydrochloride is moderately effective in reducing both systolic and diastolic pressure, but causes a greater reduction in systolic pressure.

Theoretically lowering of blood pressure may cause azotemia, cerebral vascular accidents, myocardial infarction, and, in patients with papilledema, respiratory failure or cardiac arrest. None of these complications occurred in patients who responded to therapy. One myocardial infarction occurred in a patient who was taking the drug. This elderly man, with moderately severe hypertension, had no drop in pressure on a total daily dose of 600 mg. The infarction was not thought to be due to hydralazine. It was noted that elderly and severely arteriosclerotic patients often became dizzy and felt extremely tired when their pressure was lowered. All patients who had a marked drop in pressure were initially weak and listless. This lasted for periods as long as several weeks. Patients with symptomatic hyperten-

TABLE 3.—*Systolic and Diastolic Response in Patients Taking Hydralazine*

	No. of Patients	%
Response in diastolic pressure only	2	4
Response in systolic pressure only	13	26
Response in both systolic and diastolic pressure	20	40
Significant response not obtained in either systolic or diastolic pressure	15	30

sion felt better after their pressure was lowered. They were less nervous; headaches disappeared; palpitation was relieved; and pulmonary congestion, to the point of acute pulmonary edema in some cases, was relieved. Blood pressures were maintained at a relatively constant level without postural hypotension and without wide swings of alternating hypertension and hypotension.

It is concluded that hydralazine hydrochloride is a safe drug that may be given to outpatients. It is moderately effective in lowering pressure; it is more effective in mild to moderate hypertension than in long-standing severe hypertension. The incidence of side-effects is high. These, however, are not serious and are generally transient. Hypertensive symptoms are relived when blood pressure is lowered.

THERAPY WITH HEXAMETHONIUM

Pharmacology.—Hexamethonium is a ganglionic blocking agent; it blocks both the sympathetic and the parasympathetic ganglions.[5]

Side-Effects.—The side-effects observed in 30 patients taking hexamethonium orally included postural hypotension in 23 (77%), constipation in 15 (50%), dry mouth in 9 (30%), blurred vision in 8 (27%), difficult urination in 6 (20%), diarrhea in 6 (20%), decrease in potency in 6 (20%), decrease in perspiration in 6 (20%), and anginal attack in 1 (3%). The period of observation varied from 1 to 15 months; the average was 7 months per patient. Side-effects are mainly the result of the action of the drug on ganglions. Parasympathetic block causes constipation, dry mouth, blurred vision, difficult urination, and decrease in potency. Sympathetic block results in postural hypotension. Diarrhea is the result of local irritation of the gastrointestinal tract.

Postural hypotension occurred in 75% of the patients. It varied from slight dizziness on standing to prostrating hypotension. It was unpredictable in onset and variable in occurrence. Some patients had isolated episodes after periods of uneventful therapy up to three months. Many patients had it daily, but with marked variation in severity. In one patient, severe postural hypotension persisted for seven days after discontinuing therapy, and during that time bowel movements were regular. To illustrate the great variability in response, the following example is given. One patient received a daily dose of 2,000 mg. of hexamethonium chloride. Pressures recorded in millimeters of mercury were:

Date	Recumbent Pressure	Standing Pressure
1-31-53	210/120	190/120
2- 7-53	180/100	140/ 90
2-14-53	174/ 90	160/ 90
2-21-53	260/150	120/ 80

Postural hypotension is a difficult, unpredictable, dangerous complication of therapy. Under certain circumstances it could be severely damaging to vital tissues, or even fatal.

Constipation occurred in 50% of the patients. Generally it was controlled with nightly doses of milk of magnesia. Severer cases required cascara and enemas. Bethanechol (Urecholine) chloride has been reported to aid in preventing severe constipation, but it did not prove effective in this series of patients.[1b] Cases of paralytic ileus have been reported in patients taking hexamethonium orally.[1b] It was not observed in this series. Patients must pay strict attention to the onset of constipation, and, in no case, should they allow more than 48 hours to pass without a bowel movement. To do so could cause paralytic ileus or severe hypotension.

Blurred vision is due to cycloplegia. This occurred to some extent in 26% of patients. It was generally of short duration, but in one patient it was almost constant and was extremely annoying. Temporary interference with micturition occurred in 20% of patients. It was necessary to catheterize some of these. As therapy was continued, this symptom disappeared in all but one patient, an elderly man with prostatic hypertrophy. Bethanechol chloride, sublingually, was of some benefit in the relief of urinary retention.[1b]

Diarrhea was intermittent and explosive. In some cases, there was an associated proctitis. Efforts to stop the diarrhea with opium derivatives, bismuth, and kaolin compounds were unsuccessful. It promptly disappeared when the therapy was stopped. No effort was made to treat the dry mouth, decrease in sweating, or the decrease in potency. It is reported that bethanechol chloride relieves dryness of the mouth.[1b] No evidence of chronic toxicity was observed.

Administration of Hexamethonium.—Hexamethonium may be administered either orally or parenterally. The method advocated by Freis for initiation of therapy with hexamethonium administered parenterally proved satisfactory in our series.[1b] Two precautions must be stressed; first, the patient must be in the hospital, and, second, a pressor amine, such as phenylephrine (Neo-Synephrine) hydrochloride, must be available for immediate intravenous use, since a precipitous, potentially fatal, fall in pressure may occur after the initial dose. In one patient, the pressure dropped from 260/160 to 90/50 mm. Hg within seven minutes during the intravenous administration of only 3 mg. of hexamethonium.

After the initial dose was determined, this amount was injected subcutaneously every eight hours. Increases were made as necessary. Experience in this series with parenteral administration was limited to four patients. The response was found to be much more predictable than after oral administration.

Oral administration of the drug is feasible in most patients and was used exclusively in obtaining the therapeutic results reported. Since the effective oral dose is up to 20 times the parenteral dose, it is important that confusion in method of administration does not occur. This happened in one patient. A 125 mg. dose, which was intended for oral administration, was given intramuscularly. Pressure rapidly fell to shock levels. Oral therapy was started with either a 62.5 or a 125 mg. dose twice daily. This was gradually increased to four times daily. Further increases were made as indicated by the pressure response. The range of total daily doses in this series was from 1,125 to 3,000 mg. It was felt that doses in excess of 3,000 mg. were not indicated. During therapy, frequent checks on pressure were made.

---

[5] Paton, W. D. M., and Zaimis, E. G.: Clinical Potentialities of Certain Bisquaternary Salts Causing Neuromuscular and Ganglionic Block, Nature, London 162: 810 (Nov. 20) 1948.

Some degree of tolerance to hexamethonium developed. This was more marked after parenteral than oral therapy. It varied from a mild degree to a state of complete refractoriness to therapy. Tolerance was overcome by discontinuing therapy for periods varying from two to seven days.

TABLE 4.—*Range of Fall in Pressure in Fifteen Patients Using Hexamethonium*

	Number of Patients							
	Recumbent				Standing

81-90	0		0		0		0	
91-100	0		0		1		0	
101-110	0		0		1		0	

Whether or not it is safe to start oral administration of hexamethonium in office patients is difficult to say. Actually, it is not safe and involves a calculated risk. The intelligence of the patient and the severity of the hypertension must be considered. An alternative regimen was used that insured some degree of safety. The initial dose was taken in the office and pressure readings taken hourly until the peak of action passed.

Results of Therapy with Hexamethonium.—Fifteen patients were treated for periods of time varying from 1 to 13 months; the average was 7 months per patient. The results obtained in lowering blood pressure are summarized in table 4.

In evaluating the response to therapy with hexamethonium, it was necessary to consider the pressure in both the recumbent and standing positions. Since postural hypotension of some degree occurred and was marked in many cases, it was often necessary to be satisfied with a moderate or very slight decrease in the recumbent pressure in order that the standing pressure would be within the physiological limits tolerated by the patient. The marked effect of the postural hypotension is clearly illustrated (table 4). That hexamethonium is a potent agent for lowering blood pressure is also shown.

There were four patients with malignant hypertension in the azotemic phase. All initially responded to therapy. One patient almost immediately became refractory and died. One patient was lost to the series; two obtained a short remission of several months but died. In all, the azotemia initially became worse, but then values fell to normal where they remained until death. Values for phenolsulfonphthalein excretion and urea clearance did not improve.

In addition to the theoretical complications of lowered pressure already described, hexamethonium therapy should be used cautiously in patients with glaucoma, renal insufficiency, and prostatic hypertrophy. One case of cerebral thrombosis occurred after three months of successful therapy. No case of azotemia occurred, and no evidence of the building up of toxic blood levels of hexamethonium occurred in patients with renal insufficiency. One severe anginal attack occurred when pressure was inadvertently allowed to fall to 90 mm. Hg systolic. Urinary retention was observed in one patient. No patients with glaucoma were treated. No myocardial infarctions occurred.

When patients with symptomatic hypertension had pressures lowered they felt better; headaches disappeared. In several patients, headaches were relieved even when pressures were high. Palpitation was improved. Pulmonary congestion and, in several cases, recurring attacks of acute pulmonary edema disappeared. Blurred vision, resulting from hypertensive retinopathy, was markedly improved. Blood pressure levels showed wide swings between hypertension and hypotension. It was not possible to maintain a relatively constant level.

It is concluded that hexamethonium is a potent drug for lowering blood pressure. Its use results in wide variations in pressure. When this fact, together with the dangerous side-effects and the tendency for tolerance to develop are considered, it is obvious that this is not an ideal drug for the routine treatment of hypertension. Its use should be restricted to selected cases of severe hypertension uncontrolled by other means. Hypertensive symptoms are relieved in patients whose pressures are lowered.

COMBINED THERAPY

The combination of hydralazine hydrochloride and hexamethonium was used only in patients with severe hypertension. The results reported may, therefore, be somewhat different from those reported by investigators using it in all cases of hypertension.

It was preferable to begin therapy with hexamethonium alone until a therapeutic response was obtained and then to add hydralazine hydrochloride to the regimen. At this point either of two methods of administration was effective. One was to give hexamethonium at 7:00 a. m., 1:00 p. m., and 7:00 p. m. and hydralazine hydrochloride at 10:00 a. m., 4:00 p. m., and 10:00 p. m. A more convenient method was to give the drugs simultaneously four times daily. Doses of hydralazine varied from 75 to 400 mg. and those of hexamethonium from 250 to 3,000 mg. daily.

TABLE 5.—*Range of Fall in Pressure in Fourteen Patients Using Both Hydralazine and Hexamethonium*

	Number of Patients							
	Recumbent				Standing			
Fall in Pressure, Mm. Hg	Systolic		Diastolic		Systolic		Diastolic	
0-10	3		4		1		2	
11-20	3		4		0		3	
21-30	4		3		1		6	
31-40	2		3		2		1	
41-50 Significant response	1	57%	0	43%	6	93%	2	64%
51-60	0		0		1		0	
61-70	1		0		1		0	
71-80	0		0		2		0	

Fourteen patients were treated for periods varying from 1 to 11 months; the average was 6 months per patient. The results obtained in lowering blood pressure are summarized in table 5. The clinical response in patients responding to therapy was similar to that already described when each drug was used alone.

When the results in table 5 are compared with therapeutic results using each drug alone, several facts are apparent (table 6). In the recumbent position, the percentage of patients obtaining a significant fall in systolic pressure is approximately equal in all three methods of therapy. The recumbent diastolic response is poor when hexamethonium is used alone. It is approximately equal when hydralazine hydrochloride is used alone or in combination. In the standing position, an equal number have a significant fall in systolic pressure using hexamethonium alone or in combination; hydralazine alone is less effective. The standing diastolic response is approximately the same using either drug alone, but slightly better when using a combination.

It was hoped that hydralazine would prevent or modify the wide variations in pressure during hexamethonium therapy. This was not the case. The same difficulties occurred as when either drug was used alone. A slightly greater percentage of patients had a significant response in standing diastolic pressure during combination therapy, but the main pressure drop was brought about by hexamethonium. It is felt, therefore, that combination therapy offers little advantage over therapy with hexamethonium alone.

TABLE 6.—*Comparison of the Three Methods of Therapy in Producing a Significant Fall in Blood Pressure*

	Recumbent		Standing	
	Systolic	Diastolic	Systolic	Diastolic
Hydralazine..........	66%	44%	66%	44%
Hexamethonium.......	60%	13%	93%	47%
Combination..........	57%	43%	93%	64%

COMMENT

No means was found to predict which patients would respond to therapy. Four patients who previously had sympathectomies were treated. Their response was no different from that of other patients.[4] All patients with a presumed renal hypertension responded well.

Therapeutic results obtained treating hypertension must be critically analyzed. The course of hypertensive vascular disease is in itself subject to wide variations. The emotional and stress situation varies. It is difficult to discount the placebo effect of any new medicament. Pressures taken at home and in the office may very considerably. Because of these variables, the actual advantage of therapy with these drugs in asymptomatic patients cannot be demonstrated until long-term studies of both treated and control groups are carried out.

Successful therapy with these drugs involves understanding on the part of both the patient and the physician. The patient must understand that their administration is highly individualized, requires close supervision, involves certain side-effects, and is necessarily a long-term plan of therapy. The physician must be thoroughly familiar with the pharmacology, method of administration, and side-effects of these drugs. He must not expect immediate results but be willing to increase doses gradually as indicated by therapeutic response.

SUMMARY

Hydralazine hydrochloride is a safe, moderately effective, antihypertensive drug. It can be given to office patients. The incidence of toxic effects is high, but these are generally transient. Of patients able to tolerate the drug, 66% obtained a significant fall in systolic pressure and 44% a significant fall in diastolic pressure. Thirty per cent did not respond to therapy. Patients in whom the pressure was significantly lowered were relieved of hypertensive symptoms.

Hexamethonium is a powerful, dangerous, antihypertensive drug. Its oral use results in unpredictable, wide variations in blood pressure. Starting oral therapy on office patients is not completely safe. Its main effect is brought about through postural hypotension. While standing, 93% of patients had a significant fall in systolic pressure and 47% in diastolic pressure. Patients in whom the pressure was significantly lowered were relieved of hypertensive symptoms. The use of hexamethonium should be restricted to patients with severe hypertension that does not respond to other measures.

Combined use of these drugs results in only slight advantage. The major therapeutic result in combined therapy is from hexamethonium. Elderly and severely arteriosclerotic patients do not tolerate a lowered blood pressure well. These drugs should be used with caution in such patients.

These drugs are not a completely satisfactory treatment for hypertension. They are, however, the best now available. Perhaps their greatest value will be the stimulation of investigation in similar and in new drugs.

250 E. Superior St. (11) (Dr. Hilker).

Development of the Child.—There is nothing as helpless as the newborn baby. . . . If a child is kept babyish, he will remain emotionally immature and unable to face the demands of life. He is likely to be timid and fearful but also demonstrative and appealing, always seeking someone on whom to depend. As the child grows older, the wise parent will reserve interference for major matters and leave the child to rely on himself in coping with minor problems, even if the solution is not all that could be desired. Sometimes the parent mistakes precocity for self-reliance. The child may want to interfere in everything that elders are doing but be unable to carry out the most elementary task on his own. It is a universal weakness to want to skip grades and one that appears very early. The mentality of the office boy who wants to tell the management and officials how to do their jobs, but resents the duties of an office boy, appears already in the nursery. . . . He must be content to start at the beginning and to learn step by step. He should not be permitted to acquire the interests of his elders at the expense of the normal activities of a small child. Next comes the need for companionship. Human beings are social creatures and need to live together. All social creatures have to learn to limit themselves in various ways for the sake of their neighbours. . . . It is well to remember, however, especially in these days of small families, that adults cannot serve as companions to children, for there can be no equality in the relationship. Satisfactory social adjustment can be achieved only through the give and take association of peers.—H. M. North, M.D., Development of the Child, *Medical Journal of Australia,* May 2, 1953.

VALUE OF EXERCISE IN PERIPHERAL ARTERIAL DISEASE

Lawrence H. Wisham, M.D., Arthur S. Abramson, M.D.
and
Alfred Ebel, M.D., Bronx, N. Y.

Many therapeutic agents are used in the treatment of occlusive peripheral arterial disease. Most of them are utilized to obtain an increased blood flow in the tissues of the extremities. An agent commonly used is therapeutic exercise. Exercise is done either in the form described by Buerger or that described by Buerger and modified by Allen.[1] Allen, Barker, and Hines state: "It is surprising that this method of treatment has been used so widely and yet there has been so little curiosity manifested as to whether or not it is effective in increasing the flow of blood through the extremity. The theory apparently has been that if the blood vessels were alternately emptied and distended, they would eventually accept an increased function in the transportation of blood. So far as we know there is not the slightest physiologic evidence that this occurs."[1]

It was the purpose of our studies to determine whether these exercises actually do produce an increased blood flow in the extremities of persons with and without peripheral arterial disease. It was also desired to determine quantitatively the changes in blood flow produced by a series of exercises requiring progressively greater muscular effort. The method used was that of measuring the clearance of radiosodium (Na^{24}) from tissues. The rate of this clearance reflects the effective circulation in these tissues.[2] In this way the effects of exercise were determined both during and after exercise.

Because, in a normal person, blood flow is greatly increased in muscles exercised against resistance,[2b] the effectiveness of this form of therapy in peripheral arterial disease was also studied and compared with the more commonly used forms.

METHOD

The 10 normal subjects tested in this study were volunteers. They had no symptoms of peripheral vascular disease and had palpable pedal pulses with normal oscillometric indexes. The 19 subjects who had arterial disease of the lower extremities were selected from an active peripheral vascular disease clinic on the basis of the fact that all had intermittent claudication of varying degree but no evidence of gangrene.

Muscle blood flow was determined by use of the radiosodium clearance technique, and the results were analyzed according to the method described by one of us.[2c] The clearance half life is the time taken for the activity initially present to be reduced to one half. The clearance constant (K) equals the natural logarithm of 2 divided by the clearance of half life ($T\ ½$): $K = 0.693\ /T\ ½$. Injections of 0.1 cc. of isotonic sodium chloride containing 1 to 3 μc of Na^{24} were made into the belly of the gastrocnemius muscle. A 22 gage, 1 in. (2.54 cm.) needle was used; the needle was inserted to the hilt in order to approximate the same depth of injection in the same person in all studies. A light weight Geiger counter was strapped to the leg at the site of the injected material, and the radioactivity present was recorded on an automatic register at one minute intervals. This method permitted exercise of the extremity and, at the same time, maintenance of the relationship of the counter to the site of the injected material throughout the experiment.

In all cases, the clearance rate was determined at rest. This was done after the subject had remained in the supine position in a relaxed fashion for 20 minutes. These clearance rates were determined in order to compare them with those obtained during exercise and five minutes after cessation of exercise.

Three specific forms of exercise were given in all cases. In exercise 1, while the patient was supine, the leg with the counter strapped to it was elevated by an assistant to a 60 degree angle where it was supported for two minutes. Then the assistant placed the leg in a dependent position for three minutes and then in a horizontal position for five minutes. This cycle was performed six times. At no time was the patient required to contract any leg muscles in performing these maneuvers. In exercise 2, the same procedures were followed except the patient performed active plantar and dorsal flexions of his foot 30 times a minute while the leg was in the elevated and in the dependent positions. In exercise 3, while the patient was supine, a therapist exerted considerable manual resistance to active plantar flexion. Dorsiflexion was unopposed. This resistance was offered in such a manner as to permit full plantar flexion 30 times a minute for 20 minutes. Most of the subjects complained of muscle fatigue at varying intervals. When this occurred, they were permitted to rest for one minute before exercise was resumed.

RESULTS

Controls During Exercise.—The four normal subjects in whom the clearance rate was determined during exercise showed an increase compared to the resting clearance rate. The greatest increase occurred with exercise 3. The average increase, compared to the resting rate, was 33% during exercise 1 (only two of the four studies were significant) 63% during exercise 2, and 114% during exercise 3 (table 1 and figure).

Patients with Arterial Disease During Exercise.—In eight patients with peripheral arterial disease in whom the clearance rate was found during exercise, the average increase, compared to the resting clearance rate, was 17% for exercise 1, 34% for exercise 2, and 84% for

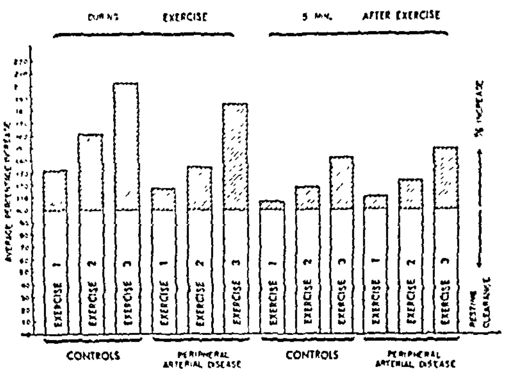
exercise 3. In two of these patients, the clearance constant during exercise 1 was 4% less than that during rest (table 2 and figure).

Controls After Exercise.—In six normal subjects in whom the clearance rate was determined five minutes after the cessation of exercise, there was an increase in the rate with all types of exercise except in one subject who showed no increase after exercise 1. The average increase, as compared to resting levels, was 7% for exercise 1, 17% for exercise 2, and 41% for exercise 3 (table 3 and figure).



Average percentage increase of clearance constant (K) in control patients and in patients with peripheral arterial disease during and after exercise.

Patients with Arterial Disease After Exercise.—In 11 patients with peripheral arterial disease in whom the clearance rate was determined five minutes after the cessation of exercise, all showed an increase after exercise 3. There were four who showed either no increase or a slower clearance rate after exercise 1 and three who showed either no increase or a slower clearance rate after exercise 2. The average increase, as compared to the resting rate, was 8.7% for exercise 1, 23% for exercise 2, and 47% for exercise 3 (table 4 and figure).

COMMENT

Rates of radiosodium clearance are reproducible with a plus or minus 15% error in the same person over varying time periods. An increase in the clearance constant of less than 15% should not be considered significant for a single study. In a series of determinations in various subjects, however, a consistent increase of even less than 15% must be considered statistically significant. If changes in the clearance constant of less than 15% are eliminated, two of four controls and five of eight patients with peripheral arterial disease showed no increase during exercise 1. During exercises 2 and 3, all those persons tested showed increases.

* Per minute.

Following cessation of exercise, the clearance rate will diminish as the metabolic effects of exercise subside. It is, therefore, possible that a well-trained person would show no increase in clearance rate five minutes after cessation of exercise because enough blood was brought to the part during and shortly after exercise to remove the accumulated metabolites quickly. This may explain the reason for which the average increase in controls after exercise was somewhat less than that for patients with vascular disease.

If increases in clearance of less than 15% are eliminated, 5 of 6 controls and 9 of 11 patients with vascular disease had no response five minutes after exercise 1; 2 of

6 controls and 6 of 11 patients with vascular disease had no response five minutes after exercise 2; and none of 6 controls and two of 11 patients with arterial vascular disease had no response five minutes after exercise 3.

These findings indicate that the mechanical concept of the passive emptying and distention of the vascular bed in an alternate fashion as a stimulus to increased blood flow must be discarded. No evidence is being presented for any long-term effectiveness of exercise as therapy. It is evident, however, that muscular contraction is an effective stimulus for increasing blood flow during and for a short time after exercise. In a general way, the blood flow increases as the muscular effort increases. Even in passive motion, as in exercise 1, it can be demonstrated electromyographically that, except in very relaxed persons, the subject makes an unconscious attempt to aid the motion of his limb.[3] This minor muscular contraction may produce in some cases minor increases in blood flow. The increasing muscular effort through exercises 2 and 3 produces an increasing blood flow, if not proportionately, at least in the same direction. The probable mechanism is through the mediation of vasodilator metabolites produced by the exercise.

SUMMARY AND CONCLUSIONS

1. Passive postural exercises do not increase blood flow significantly.
2. Active exercise is effective in increasing blood flow during and shortly after its administration.
3. The effect of exercise increases with increase in muscular effort.
4. The most effective form of exercise is that in which the muscles of the involved extremities are offered considerable resistance against their contraction.

ETHAVERINE IN THE TREATMENT OF ANGINA PECTORIS

Carl M. Voyles, M.D., Homer A. Sieber, M.D.
and
Edward S. Orgain, M.D., Durham, N. C.

In laboratory animals papaverine acts as a potent coronary vasodilator drug.[1] Studies [2] indicate that ethaverine (6,7-diethoxy-1-[3,4-diethoxybenzyl] isoquinoline), the ethyl analogue of papaverine, is a general visceral and vascular spasmolytic agent. In recent experiments concerning the coronary blood flow of quickly isolated, beating rabbit hearts, ethaverine has been shown to be equal to papaverine in peak potency but of more durable action, so that in total effect summed up over time it is more effective.[3] Ethaverine has the advantage of not being classified as a narcotic under the Harrison Act.[4] The toxicity of ethaverine is roughly one-third that of papaverine, and large doses have been given in man without untoward effect. In a previous study,[5] 16 patients with relatively stable angina pectoris were given ethaverine over periods of 4 to 20 weeks, followed by placebo therapy for corresponding periods. Seven of these 16 patients experienced marked reduction in frequency and severity of angina while taking ethaverine, and 4 patients experienced similar improvement while on placebo therapy.

MATERIAL AND METHODS

In order to avoid the common errors of physician enthusiasm and "new drug" psychological effect on the patient and because angina pectoris exhibits spontaneous variations, it was decided to perform a "double-blind" experiment for more accurate evaluation of ethaverine in this disorder. For the same reasons Greiner and coworkers [6] employed a similar technique in their evaluation of visammin (khellin) in angina pectoris. Twenty-two patients were selected from our clinic for alternate periods of treatment with ethaverine and placebo. Ages ranged from 40 to 77 years, the average age being 57 years. All had proved coronary artery disease with moderately severe to incapacitating angina pectoris. Most patients had demonstrated stable anginal patterns for several months before starting the experiment. Seventeen of the 22 patients had electrocardiographic changes consistent with coronary heart disease, and 17 had had proved or suspected myocardial infarction in the past. Each was instructed to continue those medicines, except papaverine or xanthine drugs, in use before the experiment was initiated, and care was taken that no other change in regimen was made.

Daily report cards were employed, on which patients recorded the number of attacks of angina, the number

of nitroglycerin (glyceryl trinitrate) tablets used, and whether the day was a "good," "bad," or "unchanged" one. An illustration of the daily report card used is given in the figure. This particular method of evaluating patient response to drug has been decidedly helpful; patients have been able to keep a more accurate account of angina than by other means, including a daily diary. In most instances reports were recorded in a satisfactory manner.

Two capsules, each containing 50 mg. of ethaverine, were given four times daily for a total dosage of 400 mg. Placebo capsules of identical appearance containing lactose were prescribed in the same number and in similar containers; one preparation was labeled D-47 and the other D-48. Patients were informed that the drugs in question were experimental, of unproved value, and that both drugs would be used alternately. A technician, who had no contact with the patient other than dispensing the drugs, started alternate patients on placebo or ethaverine, each patient receiving six weeks of therapy on each preparation. The physicians who evaluated the patients' response had no knowledge of which preparation patients were receiving until the entire series of patients had completed the predetermined course of treatment. Patients were seen and examined at intervals of three to six weeks. Electrocardiograms and chest roentgenograms were routinely repeated for serial changes.

RESULTS

The results of therapy with ethaverine alternating with placebo over periods of 12 weeks in 22 patients with angina are shown in the table. Two patients died suddenly as a result of myocardial infarction during the study, one at the completion of the study while on placebo, and one, not included in this series, after 30 days of therapy with placebo alone. The total number of days all patients received ethaverine was 926, and they received placebo 914 days. There are two points of interest in these findings. First, the percentage of unchanged (19.2%), good (73%), and bad (7.8%) days on ethaverine are strikingly similar to the results with placebo, 18.3% unchanged, 74.4% good, and 7.3% bad. Second, the majority of days were described as good days by patients undergoing treatment with either placebo or ethaverine.

Report card used by patients with angina pectoris during treatment with ethaverine and placebo.

The table gives each patient's total number of attacks of pain and the number of nitroglycerin tablets employed while taking each preparation. Patients 2 and 9 took nitroglycerin to prevent pain as well as to relieve pain, but this method of prophylaxis, followed through the entire study, does not influence the results. Patients 2 and 21 are the only ones who showed a signficant difference in the number of attacks of pain: the former improved by ethaverine, and the latter by placebo. The sum totals, as noted at the bottom of the table, reveal an unusual similarity in the effectiveness of the two preparations.

COMMENT

In this group of patients the ethyl analogue of papaverine has been found to be no more effective in reducing either the severity or frequency of angina pectoris than similar amounts of lactose given under "double-blind" conditions. It is interesting to note that, with few exceptions, patients were significantly improved during therapy, both with ethaverine and with placebo. Experiments of this type afford an excellent form of psychotherapy, in that a new and perhaps promising form of therapy is offered by physicians in whom patients have confidence. Considerable attention also is devoted to the patient by virtue of frequent follow-ups at relatively short intervals. It is well known that angina pectoris may be affected by many factors other than exertion alone. Outstanding examples are variations in mood, emotional upsets, degree of security, fatigue, desire and hope for improvement, food load, and exposure, particularly to cold. It has been our observation that most of the patients in this series have exhibited cyclic variations in frequency and severity of angina pectoris irrespective of the type of medication. Periods of marked improvement extending from a few days to several weeks have been observed to recur periodically. This phenomenon leads to false assumptions regarding the efficacy of any drug being given during such periods of improvement.

Undesirable side-effects thought to be related to ethaverine therapy were experienced by 3 of 20 patients while receiving 400 mg. of the drug daily during a previous study,[5] but by no patients during the course of this study. Two patients experienced mild cramping pain in the low abdomen and loose stools over a period of several days; relief followed reduction in dosage or substitution of placebo. These symptoms were not of sufficient severity to cause the drug to be permanently discontinued. One patient experienced a marked increase in frequency and severity of angina during each of two 48 hour periods of ethaverine therapy, with prompt relief following cessation of therapy in each instance.

SUMMARY AND CONCLUSIONS

In experimental animals it has been shown that ethaverine, the ethyl analogue of papaverine, has a more prolonged and effective vasodilating action on the coronary arteries than papaverine. A "double-blind" study alternating ethaverine with placebo was made in 22 patients with stable angina pectoris. The majority of patients reported subjective improvement to an equal degree with both ethaverine and placebo. Ethaverine was no more effective than placebo therapy in reducing the severity or frequency of attacks of angina pectoris. Cyclic variations in frequency and severity of angina pectoris irrespective of medication were noted in this series.

ANEMIA IN BACTERIAL ENDOCARDITIS

William B. Parsons Jr., M.D., Talbert Cooper, M.D.
and
Charles H. Scheifley, M.D., Rochester, Minn.

The frequent occurrence of anemia in bacterial endocarditis has not been sufficiently emphasized. Recognition of this association is particularly important in cases in which the use of antibiotic therapy for an undiagnosed febrile illness may have masked some of the usual symptoms and signs of the disease. Anemia and other hematological disturbances may occasionally even overshadow the more familiar manifestations of bacterial endocarditis to such a degree that the disease may be mistaken for a primary hematological disorder. Since antibiotic therapy cures most cases of subacute bacterial endocarditis, it is important that the diagnosis of anemia be made correctly and as early as possible.

The occurrence of anemia along with bacterial endocarditis is usually mentioned in descriptions of the disease. In 1927 Pepper [1] reported anemia in 19 of 20 cases of subacute bacterial endocarditis caused by nonhemolytic Streptococcus viridans. In 1939 Middleton and Burke [2] reported anemia, usually of mild degree, in 63.5% of 88 cases of bacterial endocarditis. Dowling and his associates [3] stated that a mild to moderate anemia was present in all of 25 cases of staphylococcic endocarditis. Detailed discussion of the pathogenesis of the anemia of bacterial endocarditis is beyond the scope of this paper; however, in addition to the interference with normal iron metabolism noted in anemia of infection by Cartwright and his associates,[4] factors such as toxic suppression of bone marrow function, hemolytic activity, or a hypersplenic influence may warrant consideration in some cases. Another hematological change is the occurrence in the blood of phagocytic reticuloendothelial cells (in 15 to 20% of patients with bacterial endocarditis), which, although not specific, is strong suggestive evidence of this disease. No other distinctive changes in the blood have been consistently noted.

This report is a review of a series of 200 cases of bacterial endocarditis seen at the Mayo Clinic in the years 1944 through 1949. Only cases in which clinical evidence of bacterial endocarditis was substantiated by positive blood cultures or by necropsy were included in the study. The incidence of various symptoms and signs was compared with that of anemia and other hematological findings. The duration of the disease was estimated as closely as possible to determine whether this factor bore any consistent relation to the severity of hematological changes.

RESULTS

Age and Sex.—The ratio of males to females was 2 to 1. A wide range of ages was found, with only 44% of patients between the ages of 11 and 40 years, as compared to 68% found in this age group by Middleton and Burke.[2]

History of Cardiac Abnormality.—Eleven patients were known to have congenital heart disease or a murmur present since birth. Fifty-seven patients had a history of rheumatic fever, and an additional five patients had had chorea. A group of 49 patients had been informed of the presence of a heart murmur at some previous time. One patient had been told that his heart was enlarged, and another mentioned a previous diagnosis of fibrillation. The remaining 76 patients (38%) had no history of rheumatic fever or cardiac murmur prior to the current illness.

Bacteriological Findings.—Cultures of the blood were made in 197 cases. The remaining three cases proved at necropsy to be bacterial endocarditis. In 169 cases

(84.5%), the disease was caused by streptococci. Twenty-three cases (11.5%) were caused by micrococci, two by Escherichia coli, two by Hemophilus influenzae, and one by an unidentified gram-negative bacillus. A preliminary survey of data revealed no significant differences in duration, symptoms, or hematological changes of streptococcic and micrococcic endocarditis; therefore, the cases are not considered separately according to the organisms involved. The average duration of illness for the entire series was 5.1 months.

Symptoms.—The presenting symptoms were as follows: fever, 143 cases; loss of weight (average 27 lb. [12.24 kg.]), 83 cases; chills, 66 cases; weakness, 66 cases; fatigue, 54 cases; sweats, 45 cases; anorexia, 36 cases; headache, 30 cases; malaise, 23 cases; dyspnea, 22 cases; edema of ankles, 13 cases; chest pain, 19 cases; palpitation, 5 cases; orthopnea, 5 cases; abdominal pain, 18 cases; nausea and vomiting, 9 cases; nausea alone, 6 cases; bloating, 7 cases; diarrhea, 6 cases; arthralgia, 17 cases; arthritis, 11 cases; muscular pains, 15 cases; backache, 7 cases; painful fingers, 10 cases; petechiae, 8 cases; stroke (hemiplegia, hemiparesis, hemiparesthesia), 12 cases; aphasia, 4 cases; stiff neck, 4 cases. These symptoms not only represent the principal complaints volunteered by the patients but include all significant symptoms elicited in the histories. The more frequently occurring manifestations were constitutional and nonspecific. In contrast to the series of Middleton and Burke[2] is the infrequency in our patients of symptoms related to the heart as well as to other specific organs or systems.

Physical Findings.—Temperature exceeding 100 F was recorded in 150 patients (75%). In the remaining 25%, no temperature reading of 100 F or higher was obtained. Roentgenologic examination revealed definite cardiac enlargement in 74 patients (37%), doubtful or slight enlargement in 8 (4%), and no evidence of cardiac enlargement in 118 (59%). Cardiac murmurs were heard in all patients at some time during the course of the illness. In some no murmur was audible until late in the disease, and in others a murmur was present transiently or was not believed to be suggestive of a valvular lesion.

Enlargement of the spleen, usually of minimal degree but occasionally marked, was present in 88 patients (44%). In 7 patients (3.5%) the tip of the spleen was questionably palpable, and in the remaining 105 patients (52.5%) the spleen was not palpable. Hepatomegaly, usually associated with other evidence of congestive failure, was found in 30 patients (15%). Clubbing of the fingers was present in only 34 patients (17%). Evidence of embolization (in which we arbitrarily include the presence of petechiae or Osler's nodes) was present at some time in 122 patients (61%). In a small number, the evidence was subjective; for example, a history of pain in the splenic area, pain of pleuritic nature, or painful fingertips.

Laboratory Studies.—The hemoglobin concentration was recorded in 199 patients. The values obtained on the first examination are seen in table 1. Values of less than 12 gm. per 100 cc. of blood in males or less than 11 gm. per 100 cc. in females are considered indicative of anemia. A total of 150 patients (75%) had initial hemoglobin concentrations below these lower limits of normal. Twenty-eight patients (14.1%) had concentrations of 9 gm. per 100 cc. or less. Only 14 patients (7%) had values between 13 and 15 gm. per 100 cc., whereas in a group of normal persons most of the values are in this range, particularly in a group in which males predominate, as they do in this series. The relation of hemoglobin concentrations to the duration of bacterial endocarditis, as nearly as could be estimated from the histories, is shown in table 2. No consistent relationship can be found.

Erythrocyte counts were recorded in 191 cases. The values obtained on admission are shown in table 3. Counts of less than 4 million erythrocytes per cubic millimeter are considered to signify anemia in either sex.

TABLE 1.—*Concentration of Hemoglobin (Photoelectric Method) in 199 Cases of Bacterial Endocarditis*[*]

Hemoglobin, Gm. per 100 Cc. of Blood	Males	Females	Total
15.0 and over	2	..	2
13.1-15.0	13	1	14
12.1-13.0	11	9	20
11.1-12.0	..	13	13
Total nonanemic patients	26	23	49
11.1-12.0	29[†]	..	29
9.1-11.0	63	30[‡]	93
7.1- 9.0	9	13	22
7.0 or less	5	1	6
Total anemic patients	106	44	150

[*] No determination made in one case.

[†] In men concentrations of less than 12 gm. per 100 cc. indicate anemia.

[‡] In women concentrations of less than 11 gm. per 100 cc. indicate anemia.

TABLE 2.—*Concentration of Hemoglobin and Duration of Disease in 200 Cases of Bacterial Endocarditis*

	Average Duration, Months		
Hemoglobin, Gm. per 100 Cc. of Blood	Males	Females	Entire Group
15.0 and over	0.5	...	0.5
13.1-15.0	4.0	(9.0)[*]	4.0
11.1-13.0	5.6	3.9	4.9
9.1-11.0	4.4	4.6	4.5
7.1- 9.0	6.2	3.1	4.0
7.0 or less	3.1	(1.5)[*]	3.1

[*] One patient only.

A color index was not calculated for each patient, but the anemia, when present, tended to be slightly hypochromic, although the cells were normochromic in many. These observations were confirmed by morphological examination of blood smears. Leukocyte counts were performed on all 200 patients. A leukocyte count greater than 10,000 cells per cubic millimeter was noted in only 72 patients (36%), of whom 52 had counts between 10,000 and 15,000 cells per cubic millimeter. One hundred fourteen patients (57%) had initial counts of between 5,000 and 10,000 leukocytes per cubic millimeter, and 14 patients (7%) had counts of less than 5,000 cells per cubic millimeter.

Stained smears of peripheral blood from 122 patients were examined. In most smears, nothing of diagnostic significance was noted. The most frequent abnormalities in the erythrocytes were increased regeneration, increased rouleaux formation, and hypochromasia. Toxic granulation of the polymorphonuclear leukocytes, left-shifted granulocytes, and myeloid immaturity were frequently seen. Reticuloendothelial cells were observed in 37 patients, with evidence of phagocytosis in 11 of these. In only a small percentage of cases was the first drop of blood from the ear lobe examined. On the basis of experience in recent years, it is reasonable to assume that a higher incidence of phagocytic reticuloendothelial cells would have been found if the examination had been performed on a smear prepared from the first drop of blood.

Examinations of sternal marrow were not performed routinely on patients in this series. This examination was carried out as a part of the differential diagnostic survey in six patients, but no consistent changes were observed. The erythrocyte sedimentation rate (Westergren method) was recorded for 189 patients. The rates were 30 mm. or less per hour in 14 patients, between 31 and 60 mm. per hour in 52 patients, between 61 and 100 mm. per hour in 83 patients, and more than 100 mm. per hour in 40 patients.

COMMENT

There are no hematological findings that are particularly diagnostic of bacterial endocarditis. We wish to emphasize the frequency with which anemia occurs in bacterial endocarditis and to stress the importance of anemia as a diagnostic point when some of the more familiar manifestations of the disease may be absent. The anemia may be of sufficient degree to simulate a primary hematological disorder, as illustrated by selected cases from this series.[5] If bacterial endocarditis is suspected clinically, the finding of phagocytic reticuloendothelial cells in the first drop of blood obtained from the ear constitutes strong confirmatory evidence, although this finding may be present in other conditions.

TABLE 3.—*Erythrocyte Counts in 191 Cases of Bacterial Endocarditis*

Cells per Cu. Mm., Millions	Males	Females	Total
5.0 or over	1	1	2
4.0-5.0	57	27	84
3.0-4.0	57	30	87
2.0-3.0	10	6	16
2.0 or less	2	0	2
Total	127	64	191

Anemia, which was present in 75% of patients in our series, was exceeded in frequency only by cardiac murmurs and positive blood cultures. The incidence of fever (75%) was the same as that of anemia. Anemia was present more frequently than evidence of embolization (61%), splenomegaly (44%), cardiac enlargement (37%), or clubbing of the fingers (17%). From these figures, it will be noted that the manifestations classically associated with bacterial endocarditis were present in a substantially smaller percentage of cases in our series than in previous reports in the literature, based on necropsy material. Several reasons for this difference are apparent. The manifestations in our patients were tabulated at an earlier stage of the disease. Furthermore, in a series of patients examined post mortem, evidence of embolization, splenomegaly, or cardiac enlargement that was not apparent clinically might be found. It is possible that antibiotic therapy, which many patients receive before the diagnosis is reached, may alter the clinical picture from that observed before the advent of antibiotic therapy. It is believed that our data, tabulated from clinical evaluation rather than from necropsy findings, represent more accurately the disease as seen by the clinician.

Some of the patients in this series were anemic before they came to the clinic and had been treated with iron, liver extract, or blood transfusions. This was true of at least 28 patients (14%). Despite the fact that a number of patients had received transfusions of whole blood a short time before coming to the clinic, no adjustment was made for the resultant transient elevation of hemoglobin and erythrocyte values in the foregoing analysis. Liver or iron therapy, of course, proved ineffective in correcting anemia of this type.

Many patients have been seen in recent years after they had received one or more short courses of antibiotic therapy for a febrile illness that later proved to be bacterial endocarditis. Inadequate antibiotic therapy may temporarily suppress the fever and render the blood stream sterile but does not eliminate the bacterial endocarditis. In the absence of fever, bacteremia, and the less common manifestations of bacterial endocarditis, a soft systolic murmur may not be considered significant. In view of these observations, anemia assumes greater importance in the diagnosis of bacterial endocarditis. It has long been said that if the patient has a cardiac murmur and an unexplained fever, bacterial endocarditis should be considered; to this might be added that if the patient has a cardiac murmur and an unexplained anemia, even without fever, bacterial endocarditis should be considered. Because of the few cases in which a murmur is transient, is first noted late in the course of the disease, or is not considered suggestive of a valvular lesion, it might also be said that if the patient has an unexplained fever and anemia, despite the absence of a cardiac murmur suggestive of valvular heart disease, bacterial endocarditis should be considered. The common practice of attributing a soft systolic murmur to anemia can be misleading in such cases. Detailed reports of cases from our series that illustrate these maxims are to be published.[5]

SUMMARY

In a series of 200 cases of bacterial endocarditis, anemia was found on initial examination in 150 patients (75%). Anemia was commoner than evidence of embolization (in 61%), splenomegaly (in 44%), cardiac enlargement (in 37%), or clubbing of the fingers (in 17%). Since inadequate antibiotic therapy may temporarily suppress the fever and bacteremia, the association of a cardiac murmur and an unexplained anemia should suggest the possibility of bacterial endocarditis. Because occasionally cardiac murmurs may be absent in bacterial endocarditis, the association of an unexplained fever and anemia should also suggest the possibility of this disease.

HUMAN THROMBIN AS VEHICLE OF INFECTION IN HOMOLOGOUS SERUM HEPATITIS

The increasingly wide use of blood and blood products in medical practice has carried with it an increasing risk of homologous serum hepatitis (viral hepatitis B) among recipients of these materials. With the development, by Cohn and co-workers,[1] of techniques for the fractionation of the plasma proteins and with the widespread clinical use of the blood fractions thus produced, the question of whether these fractions might transmit homologous serum hepatitis has become a pressing one. The gamma globulin fraction, as prepared by ethyl alcohol (ethanol) precipitation, appears to be free of the agent of homologous serum hepatitis,[2] despite the fact that individual lots of gamma globulin may represent the pooled plasmas of thousands of donors.[3] It would appear that, in the preparation of this fraction by ethyl alcohol, the virus is inactivated, eliminated, or neutralized.[3] The albumin fraction prepared in this way has not been shown to contain the virus, and the albumin concentrates now in use are apparently free of it.[4] In any event, it has been demonstrated that this product can withstand the degree of heating required to inactivate the virus.[5] Homologous serum hepatitis has not been reported following the use of antihemophilic globulin, as prepared by the ethyl alcohol precipitation method.

The widespread acceptance of preparations of thrombin for use in local hemostasis is an indication of the value of these preparations in surgical procedures. The human thrombin used in the cases reported here was prepared from Cohn's "Fraction III-2" by the ethyl alcohol fractionation method. Prothrombin is first isolated and is subsequently activated to thrombin with thromboplastin, in the form of a placental extract. After Seitz filtration the thrombin is dried from the frozen state, usually in the containers in which it is to be distributed.

This report is concerned with the appearance of homologous serum hepatitis following the use of thrombin thus prepared from human plasma pools. Several hospitals in the New England area were affected. An outbreak in one of these has already been reported.[6] This was not substantiated by study of the material in volunteers. The present report concerns epidemiological observations on the epidemic in another of the affected hospitals, together with the results of studies in volunteers on two lots of the suspected thrombin. Discussions with the manufacturer revealed that there had been no unusual features in the production of the two lots under study. Both lots were processed at about the same time, and the placental extract used was the same in both cases. This extract was not used for any other lots, and none remained that could be examined for the presence of the agent of homologous serum hepatitis.

OUTBREAK IN MAINE GENERAL HOSPITAL

Since 1944 cases of viral hepatitis that could be attributed to previously transfused blood or plasma have been seen at this hospital with a frequency of at least one per year; the maximum number in any one year has been three. During 1950, however, and up to April, 1951, 18 cases of homologous serum hepatitis were observed. The available data indicated that the disease had been transmitted by some agent or technique used in the hospital. Of these 18 patients, 15 had undergone operations by the neurosurgical service and 3 by the general surgical service. These had been performed, in the latter three cases, during March and September, 1950, and, while all three had received either blood or plasma, none, as far as could be determined, received human thrombin. These three cases may be considered to reflect the endemic incidence of the disease at this institution.

Prior to this sharp rise in incidence of hepatitis, thrombin of bovine origin had been used at the hospital. Unfortunately, the exact date on which human thrombin tion of the polymorphonuclear leukocytes, left-shifted granulocytes, and myeloid immaturity were frequently seen. Reticuloendothelial cells were observed in 37 patients, with evidence of phagocytosis in 11 of these. In only a small percentage of cases was the first drop of blood from the ear lobe examined. On the basis of experience in recent years, it is reasonable to assume that a higher incidence of phagocytic reticuloendothelial cells would have been found if the examination had been performed on a smear prepared from the first drop of blood.

The increasingly wide use of blood and blood products in medical practice has carried with it an increasing risk of homologous serum hepatitis (viral hepatitis B) among recipients of these materials. With the development, by Cohn and co-workers,[1] of techniques for the fractionation of the plasma proteins and with the widespread clinical use of the blood fractions thus produced, the question of whether these fractions might transmit homologous serum hepatitis has become a pressing one. The gamma globulin fraction, as prepared by ethyl alcohol (ethanol) precipitation, appears to be free of the agent of homologous serum hepatitis,[2] despite the fact that individual lots of gamma globulin may represent the pooled plasmas of thousands of donors.[3] It would appear that, in the preparation of this fraction by ethyl alcohol, the virus is inactivated, eliminated, or neutralized.[3] The albumin fraction prepared in this way has not been shown to contain the virus, and the albumin concentrates now in use are apparently free of it.[4] In any event, it has been demonstrated that this product can withstand the degree of heating required to inactivate the virus.[5] Homologous serum hepatitis has not been reported following the use of antihemophilic globulin, as prepared by the ethyl alcohol precipitation method.

The widespread acceptance of preparations of thrombin for use in local hemostasis is an indication of the value of these preparations in surgical procedures. The human thrombin used in the cases reported here was prepared from Cohn's "Fraction III-2" by the ethyl alcohol fractionation method. Prothrombin is first isolated and is subsequently activated to thrombin with thromboplastin, in the form of a placental extract. After Seitz filtration the thrombin is dried from the frozen state, usually in the containers in which it is to be distributed.

This report is concerned with the appearance of homologous serum hepatitis following the use of thrombin thus prepared from human plasma pools. Several hospitals in the New England area were affected. An outbreak in one of these has already been reported.[6] This was not substantiated by study of the material in volunteers. The present report concerns epidemiological observations on the epidemic in another of the affected hospitals, together with the results of studies in volunteers on two lots of the suspected thrombin. Discussions with the manufacturer revealed that there had been no unusual features in the production of the two lots under study. Both lots were processed at about the same time, and the placental extract used was the same in both cases. This extract was not used for any other lots, and none remained that could be examined for the presence of the agent of homologous serum hepatitis.

OUTBREAK IN MAINE GENERAL HOSPITAL

Since 1944 cases of viral hepatitis that could be attributed to previously transfused blood or plasma have been seen at this hospital with a frequency of at least one per year; the maximum number in any one year has been three. During 1950, however, and up to April, 1951, 18 cases of homologous serum hepatitis were observed. The available data indicated that the disease had been transmitted by some agent or technique used in the hospital. Of these 18 patients, 15 had undergone operations by the neurosurgical service and 3 by the general surgical service. These had been performed, in the latter three cases, during March and September, 1950, and, while all three had received either blood or plasma, none, as far as could be determined, received human thrombin. These three cases may be considered to reflect the endemic incidence of the disease at this institution.

Prior to this sharp rise in incidence of hepatitis, thrombin of bovine origin had been used at the hospital. Unfortunately, the exact date on which human thrombin was substituted for the bovine material is unknown. Shipments of human thrombin were received on May 24, 1950, June 27, 1950, and July 25, 1950; these were stored in the hospital pharmacy for an unknown period, until the supply of bovine thrombin in the operating room was exhausted. From the amounts of thrombin solution recorded on the anesthesia sheets, as contrasted with the amounts of bovine thrombin generally used, it appeared that all the neurosurgical patients in whom hepatitis developed had received human thrombin at the time of operation. The serial numbers of the thrombin solutions used were not recorded on the patients' charts. Between July 13, 1950 (the date of operation of the first patient in whom hepatitis later developed), and Jan. 8, 1951, 75 persons were operated on by the neurosurgical service. Of these, 48 received thrombin at operation and 27 received no thrombin. Among the former group, there were 15 cases diagnosed as homologous serum hepatitis (31%), while in the latter group no cases were found.

---

† Deceased.

This investigation was conducted in part under the sponsorship of the Commission on Liver Disease, Armed Forces Epidemiological Board, and supported in part by the Office of the Surgeon General, Department of the Army.

These studies were made possible through the cooperation of the Bureau of Prisons, United States Department of Justice, the staff of the Federal Penitentiary, McNeil Island, Washington, and the New Jersey State Department of Institutions and Agencies.

From the Maine General Hospital (Drs. Porter, Shapiro, and Maltby); the Children's Hospital of Philadelphia and the Department of Pediatrics, School of Medicine, University of Pennsylvania (Drs. Drake, Barondess, Bashe, and Stokes); and the Laboratory of Biologics Control, National Microbiological Institute, National Institutes of Health, United States Public Health Service, Department of Health, Education, and Welfare (Drs. Oliphant, Diefenbach, Murray, and Leone). Dr. Barondess is a Research Fellow, Communicable Disease Center, and Dr. Bashe, a Research Fellow, National Institutes of Health, United States Public Health Service.

It appears that, even after the human thrombin was introduced into the operating rooms, there were some operating days on which bovine thrombin was used in an effort to use up these stocks. These facts are reflected in a review of our records, revealing several instances in which patients operated on the same day received thrombin without hepatitis developing, but there is no instance in which two or more patients were operated on the same day and received thrombin, with subsequent development of hepatitis in only one. It is perhaps of some significance that two donors, whose blood had been administered to two patients in whom hepatitis later developed, had donated blood two and three times, respectively, within the previous two years, and hepatitis developed in none of these recipients.

TABLE 1.—*Outline of Cases of Homologous Serum Hepatitis*

Case	Diagnosis	Date of Surgery	Procedure	Blood Transfusion, Cc.	Onset of Hepatitis	Result	Incubation Period, Days
1	Ruptured lumbar disk	July 13, 1950	Laminotomy	0	Nov., 1950	Mild, recovered	109
2	Cord tumor suspect	Aug. 2, 1950	Laminectomy	500	Early Nov., 1950	Mild, recovered	90
3	Ruptured disk	July 27, 1950	Laminotomy	500	Nov. 2, 1950	Moderately severe, recovered	98
4	Traumatic transverse myelitis	Aug. 17, 1950	Exploratory laminectomy	750	Nov. 26, 1950	Mild, recovered	101
5	Ruptured disk	Aug. 18, 1950	Laminotomy	0	Dec. 14, 1950	Mild, recovered	119
6	Cord tumor	Aug. 28, 1950	Laminectomy	1,000	Dec. 14,1950	Moderately severe, recovered	109
7	Ruptured disk	Sept. 6, 1950	Laminotomy	0	Dec. 6, 1950	Mild, recovered	92
8	Skull fracture	Sept. 21, 1950	Craniotomy	0	Dec. 25, 1950	Mild, recovered	95
9	Meningioma	Nov. 1, 1950	Craniotomy	1,000	Dec. 25, 1950	Died, autopsy	54
10	Trigeminal neuralgia	Nov. 6, 1950	Retrogasserian neurectomy	500	March 29, 1951	Moderately severe, recovered	143
11	Reticulum cell sarcoma	Nov. 30, 1950	Laminectomy	500	March 21, 1951	Died, metastasis to liver	112
12	Ruptured disk	Nov. 30, 1950	Laminotomy	500	Jan. 24, 1951	Died, autopsy	55
13	Ruptured disk	Dec. 8, 1950	Laminotomy	0	March, 1951	Mild, recovered	82
14	Intracranial aneurysm	Dec. 11, 1950	Craniotomy	1,500	June 1, 1951	Mild, recovered	171
15	Ruptured disk	Jan. 8, 1951	Craniotomy	1,500	March 30, 1951	Mild, recovered	81

The cases in this outbreak are summarized in table 1. It will be seen that the incubation periods ranged from 54 to 171 days; the latter figure is somewhat long in terms of the usual incubation periods seen in this disease, but the case is included because the man had known exposure to the icterogenic thrombin solution and because the incubation period in his case, while slightly longer than usual, was not long enough to make it highly improbable that hepatitis was contracted at operation. The onset in most of the cases was insidious, and several patients were unaware of the hepatitis until it was discovered on follow-up physicial examination.

There were three fatalities in the series; one of these was apparently unrelated to the hepatitis. When this case is omitted, the fatality rate in this outbreak was 11%. It is of some interest that the two patients who died of hepatitis had the shortest incubation periods, 54 and 55 days, respectively. While this suggested a relationship between incubation period and severity of illness, this was not borne out by the cases with the longest incubation periods, since these were not especially mild in relation to cases with moderate incubation periods. There appeared to be no relation between severity of illness and the amount of thrombin solution used at operation.

VOLUNTEER STUDIES

Because of the close epidemiological correlation between the use of human thrombin and the occurrence of homologous serum hepatitis at the Maine General Hospital, and in view of the lack of specific tests or methods for isolating the virus or of any demonstrable susceptibility in animals, it was deemed advisable to test samples of the thrombin in volunteers. Two volunteer studies were done, using in experiment A a sample of the thrombin that had been used at the Maine General Hospital and in experiment B a sample from the other lot incriminated in the other New England hospitals affected but obtained directly from the manufacturer. Institutionalized healthy male volunteers, over 19 and below middle age, who had been screened on the basis of medical history, physical examination, and a battery of liver function tests, including urine bilirubin, urine urobilinogen, serum bilirubin, thymol turbidity, thymol flocculation, and cephalin flocculation, were used as experimental subjects. The samples of dried thrombin were dissolved in a solution of sterile isotonic sodium chloride to final concentrations of 500 units per cubic centimeter in experiment A and 1,000 units per cubic centimeter in experiment B. Each volunteer received a subcutaneous injection of solution representing 1,000 units of thrombin. These men were then given, at intervals of one week or less, physical examinations and complete batteries of liver function tests. They were admitted to the institution hospitals when jaundice or other signs and symptoms of hepatitis developed. All volunteers were under medical surveillance for four to five months after inoculation.

The results of the two experiments are summarized in table 2. It will be seen that in almost 50% of the total volunteer group hepatitis with jaundice developed, and that in an additional 20% hepatitis without jaundice developed. The illnesses, in general, were mild to moderate, with the exception of one man in experiment A. This person, 28 years of age, was severely ill for seven days and remained icteric, with anorexia and extreme fatigability, for two months. He was finally discharged as recovered about 80 days after onset. In the cases described as hepatitis without jaundice, one or more of the following conditions developed after the indicated incubation periods: malaise, anorexia, nausea, or abdominal pain. Abnormalities in serum bilirubin and serum flocculation tests, sufficient to establish the diagnosis of hepatitis, developed in all of these cases.

Table 2.—*Incidence of Homologous Serum Hepatitis in Volunteers After Subcutaneous Administration of 1,000 Units of Human Thrombin*

Experiment	Lot	Volunteers	Hepatitis With Jaundice	Incubation Period, Days	Hepatitis Without Jaundice	Incubation Period, Days	Total No. of Cases of Hepatitis
A	1	5	2	77, 77	2	43, 59	4
B	2	10	5	73, 76, 78, 89, 101	1	About 100	6
Total............		15	7		3		10

COMMENT

These findings confirm the presence of the agent of homologous serum hepatitis in the samples of thrombin tested. In addition, they provide conclusive evidence that the cases of homologous serum hepatitis at the Maine General Hospital were due to the batch of thrombin in use there in 1950. That these cases concerned primarily neurosurgical patients, when considered in relation to cases of patients with homologous serum hepatitis in the other hospitals who were also convalescent from neurosurgical procedures, is a reflection of the extent to which gelatin preparations soaked in thrombin solutions are used in such procedures, in contrast to their use in general surgery or in other divisions of general hospitals.

On the basis of the evidence available it is not possible to state whether the virus was originally present in the plasma used for the manufacture of this thrombin, and escaped through the fractionation process, or whether it was accidentally introduced through the placental extract. The fact that the same extract was used in the preparation of both virus-contaminated lots suggests that the placental extract may well have been the source of the icterogenic activity of this thrombin.

In the light of past experiences, reported and unreported, the indiscriminate use of blood fractions whose safety has not been demonstrated must be viewed with grave concern and their value weighed carefully against the calculated risk of inducing homologous serum hepatitis in recipients of such biological materials. It seems obvious that all commercial preparations containing human fluids or blood products must be considered as potential sources of homologous serum hepatitis until some method for demonstrating the presence or absence of the causative virus in them has been developed.

SUMMARY AND CONCLUSIONS

An outbreak of homologous serum hepatitis (viral hepatitis B) among patients of the neurosurgical service of a general hospital is reported. The relation of this epidemic to a batch of human thrombin used at the hospital is established both by epidemiological investigation and by demonstration of the agent of homologous serum hepatitis in the thrombin, through studies in volunteers. Evidence of the presence of this virus in another batch of human thrombin obtained directly from the manufacturer was obtained by means of volunteer studies, and possible mechanisms of contamination of these lots of thrombin are briefly considered.

Caution appears justified in the use of thrombin of human origin, as well as in the use of other human blood products. Bovine thrombin is the hemostatic agent of choice, in view of the lack of danger of homologous serum hepatitis following the use of this material.

1740 Bainbridge St. (46) (Dr. Stokes).

Pancreatic Pain.—Pancreatic pain is characterized by its posterior site, its exacerbation at night, and, when the patient is in the supine position, its relief when the trunk is flexed or when pressure is applied to the epigastrium, its persistence, and the requirement of narcotics for relief. The pain originates in an organ, which is peculiar with respect to its innervation. The pancreas spreads across such an area that it is innervated by both splanchnic nerves, but, in addition, somatic pathways may be involved because most of the anterior surface of the pancreas is covered by parietal peritoneum, which blends with the anterior layer of the transverse mesocolon. The localized perforation of an ulcer onto the pancreas produces a localized type of pain. More severe involvement of the pancreas, such as acute diffuse interstitial pancreatitis, may produce a localized pain; but, in addition, it may produce extensive necrosis of mesenteric fat which may cause the pain to spread to many other parts either caudad or cephalad. . . . The pain of carcinoma of the pancreas frequently depends on the degree of infiltration of the lesion. The pain patterns of pancreatic disease are thus dependent on several factors other than the site of the organ. In the lesion that is localized, as is focal pancreatitis, which may result from chronic perforation of a peptic ulcer, the pain is referable to the head or to the body of the pancreas. If the tail of the pancreas is involved by a malignant lesion of the stomach or by perforation of an ulcerating malignant lesion of the stomach, the pain may be referred to the left lower quadrant of the abdomen. In cases in which pancreatitis is localized in the head of the pancreas, the pain may be referred only to the right and posteriorly, and, because the organ is innervated bilaterally, diffuse disease involving head, body, and tail of the pancreas may produce an encircling or girdle type of pain.—L. A. Smith, M.D., Pain Patterns in Diseases of Upper Part of the Abdomen, *Proceedings of the Staff Meetings of the Mayo Clinic,* July 29, 1953.

EVACUATION AND CARE OF CASUALTIES IN AIRCRAFT

Brig. Gen. M. S. White

and

Major Robert W. Merkle, U. S. A. F., Langley Air Force Base, Va.

The most pressing problem facing the nation today is the maintenance of adequate defense forces for security within the national economy. In order to reach this goal, we must examine the usefulness of new ideas from all fields of activity. Throughout the ages, we have seen that both the strategy of warfare and the progress of civilization in peacetime are directly dependent on changes in transportation. With the growth of air transportation, we must orient ourselves to the impact this latest advance will have on the nation's medical problems in peace and war.

One of the most challenging developments in air transportation has been rotary wing aircraft, the helicopters. These aircraft, in addition to having some of the qualities of fixed wing aircraft, have the unique capability of taking off or landing from virtually any surface. Our vision must not be so limited, however, that we speak only of the helicopter in this connection. Research is now in progress that will make fixed wing aircraft capable of similar take-off and landing performance. In aviation, the impossible of yesterday may be the obsolete of tomorrow.

The helicopter's many uses by enthusiastic military and civilian agencies have been described in recent months by all news mediums. Now, as with all new drugs, equipment, or procedures in medicine, we must follow the first flush of enthusiasm with an appraisal of the actual capabilities of this new form of air carrier. We must determine how the helicopter can be used in the broad complex of medical care.

The basic problem of peacetime medical care is not different from that of war. This problem is the timely bringing together of the physician, the patient, and the means of treatment. In military and civilian groups, medical care revolves around large medical units located at centers of population. Progressively smaller units extend from these centers. At the periphery, in civilian medicine, the country physician practices alone in a sparsely settled community, without the facilities of a group clinic or a health center. In military medicine, his counterpart is the surgeon located at the fringe of battle or at an isolated station.

To analyze the influence of the helicopter on these systems, the difference between an air and a surface carrier must be clarified. In the past this has not been done successfully because of attempts to make direct comparison of the helicopter to the truck. Evaluation was based on the helicopter's performance over the same routes, at the same distances, and to and from the same places served by trucks. The fallacy of this is the failure to recognize that those distances and routes were first determined by the capabilities of the truck. To correct this, we must appreciate the distinct formula of aviation. An aircraft's capacity to travel great distances simplifies all the processes of a transportation system; it reduces the frequency of stops, the time in transit, and the size of control and administrative systems required. In addition, long-range aircraft can provide the means for processing or care while in transit, whether a perishable food, a television news film, or a human casualty is being transported. With these advantages, however, air transportation has been handicapped because of the need for open ground for terminals. The helicopter can meet the long-range carrier at these terminals and can transport cargo or passengers to and from the battle front or metropolitan center. This junctional operation makes possible fully effective air transportation in all the problems of movement and, in turn, related problems of medical care.

One example of movement in medical care is shown in figure 1, the system of casualty evacuation now used by the military services. From the battle line, casualties are moved by any available means to the first treatment site, usually the battalion aid station or a regimental collecting station. From these, evacuation is made by ground vehicle or helicopter to a clearing station close to, or combined with, a surgical hospital. There casualties have all the advantages of early lifesaving care close to the front lines. Those who can be returned to duty in a short time are usually retained at this site. Others are removed, as shown, to evacuation and field hospitals farther behind the front lines but still in the combat zone. The combat zone normally varies in depth from 50 to 100 miles. Patients requiring further care are carried by hospital trains, ground ambulances, or air transports to the communication zone. There treatment is continued in general hospitals, hospital centers, and convalescent centers.

This system has saved lives and conserved manpower because of the coordinated efforts of the medical and transportation personnel of all the military services. The advantages of good forward surgical care and rapid transportation have resulted in less than 5% of all wounded being discharged because of disability.[1] This record speaks for itself. The evacuation system was designed by Major Jonathan Letterman 100 years ago. It was developed on a pattern that had many way stops for treatment facilities. The capabilities of the transport carriers, the mule-drawn wagons and the primitive railways used during the Civil War, determined the location of treatment units. The principles of this evacuation system, requiring a balanced interrelationship of its component factors of patient, carrier, and treatment facilities, are still valid for any plan of evacuation.

Figure 2 shows the possibilities of complete use of the air carrier. In this system, casualties would receive first-aid treatment and then be evacuated to an emergency treatment site by helicopter or other light aircraft. Evacuation here is an extra service obtained from aircraft that serve the primary function of transporting blood, sup-

---

Read before the Section on Military Medicine at the 102nd Annual Session of the American Medical Association, New York, June 3, 1953.

[1] Hays, S. B.: The Army Medical Service, U. S. Armed Forces M. J. 4: 167-174 (Feb.) 1953.

plies, personnel, or equipment to the front. After appropriate treatment, the majority of the patients would be transferred to larger aircraft, which also had brought troops or supplies forward. These air carriers would bypass the present medical care stations of the combat zone, depositing casualties at well-equipped and well-staffed hospitals in rear areas. In some instances, casualties could be evacuated directly from forward areas reached by certain types of assault aircraft, as shown by the top arrow in figure 2. Use of the helicopter-airliner combination would eliminate many of the medical facilities and supplementary means of transportation now used in the combat zone. This is especially important, because more than 70% of all the wounded in Korea require hospitalization outside of the combat zone.[1] The combat area would actually require only emergency treatment units and stand-by facilities that might be needed in the event of a catastrophe or the occasional breakdown that may occur in any movement system.

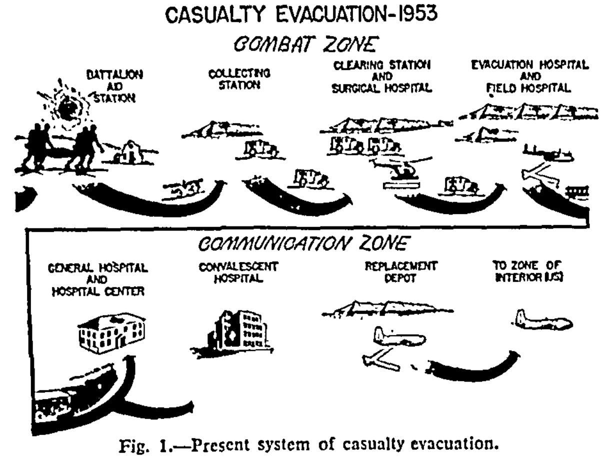

Fig. 1.—Present system of casualty evacuation.

If air transportation were developed to its maximum potential, even greater economies would be effected. Large airliners could be converted to aerial hospitals of 100 beds, instead of serving only as ambulance planes. As shown in figure 3, these hospitals would be complete, possessing wards, operating and treatment rooms, kitchens, laboratories, and morgues. Facilities of this type could be made available by use of light, portable equipment to convert the interior of the aircraft for return movement after the forward delivery of personnel or supplies. This combination of care and evacuation in aircraft, formerly performed in hospital ships, would permit almost all wounded to be returned directly to the United States without definitive hospitalization overseas. Time would be saved by elimination of the necessity to relocate civilian medical effort, and the cost of medical care at the front would be reduced. These savings would more than compensate for the manpower conservation supposedly accrued to a commander by retention of a great percentage of his wounded men in the battle area until they are well. Such retention would be unnecessary, as air transportation would still permit rapid return of fit personnel to combat from rear areas well below the time-space factors formerly used for surface transport.

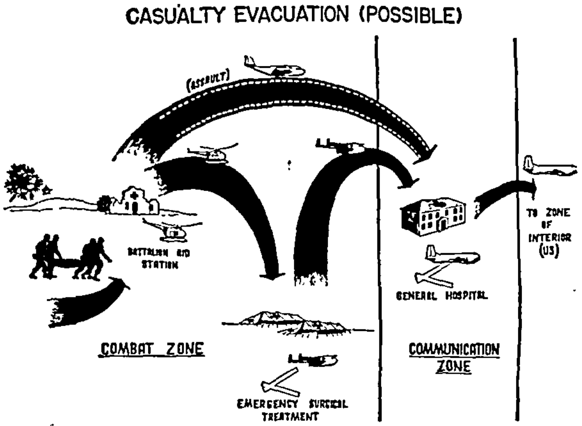

Fig. 2.—Proposed system of casualty evacuation.

Incorporation of this plan in our medical planning for the future presents the attractive possibility of practically no dislocation of the civilian medical economy in war. Civil and government facilities would be built and planned in peace for the loads of war. Physicians normally caring for the military and civilian population, as well as those readied for civilian defense needs, would continue at their routine duties. Between this remote possibility and present requirements, however, there is certainly some level at which an immediate goal can be established. The many details and specific decisions required for this are a task for the Department of Defense; nevertheless, these matters demand the attention of all physicians, for some of the same principles apply to the problems of peacetime medical care, especially with regard to sparsely settled areas. The junctional use of helicopters with airliners and distribution points provides the means of disseminating medical science and care to all areas of the nation. In addition, disasters, whether man-made or natural, affecting large groups of the population could be handled either by medical support to, or mass evacuation from, the involved areas.

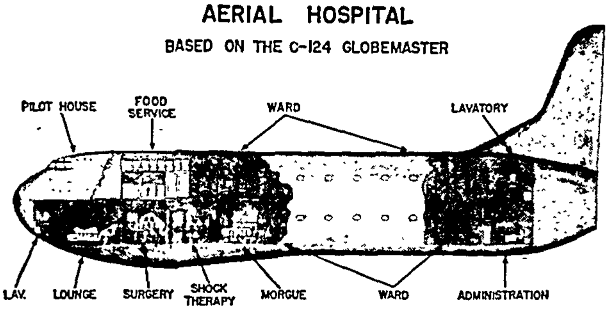

Fig. 3.—Cross section of hospital plane showing facilities for patient care in transit.

As physicians, in this period of international tension, it is appropriate that we consider these developments in air transportation in relation to future planning and air power in general. New techniques of warfare, if we cannot prevent war, will multiply our medical problems. Military medicine will be revolutionized. The success of any new evacuation technique will depend largely on the degree of air supremacy we are able to achieve. Without air supremacy it will be impracticable to have any system of evacuation, any system for combat, or even any war. If an aggressor nation should gain air superiority, it would be futile to plan evacuation of casualties by hospital train or ground ambulance. It would be futile to plan to move troops or patients over torn-up roads, bridges, and rail beds. Obviously, air power must be developed to such a degree that we as a nation can survive. As a by-product of the necessary growth of air power, increased air transportation by both helicopters and airliners can be applied to the problems of medical care. More important, its application to defense can benefit the national economy by permitting reduction of permanent military forces. In order to support small standing forces, it would only be necessary to have reserves of civilian militia that could be alerted for air transport to any trouble area. This, with air power's advantages of flexibility, surprise, and immense striking power would be a forceful deterrent to war and, to some extent, a guarantee for peace.

SUMMARY AND CONCLUSIONS

Transportation through the ages has changed the strategy of war and the activities of peace. The unique capability of helicopters, combined with larger air carriers, provides the means to furnish civilian and military medical care at great economies in personnel and facilities. Air transportation reduces the need in evacuation of wounded for many treatment units formerly required because of the limited facilities of surface carriers. Air transportation can also provide care in transit. The full acceptance of the helicopter-airliner combination would permit elimination of many medical facilities and supplementary means of transportation now used in combat zones. Additional savings to the nation's medical economy could be obtained by the use of aerial hospitals. There would be practically no relocation of civilian medical effort in war.

In peacetime the combined use of helicopters and airliners would facilitate medical care in all areas of the nation, as well as provide support in any disaster. The growth of air power would also aid total national economy by permitting a reduction in permanent military forces through development of a civilian militia reserve that could be easily transported by air.

Each of us, civilian or military man, has a personal responsibility to participate in planning for our country's future. We must properly use air power to improve medical care, save medical manpower, and advance the national economy, in peace or war.

NOTES ON A SERIES OF BRAIN TUMORS

Francis C. Grant, M.D., Philadelphia

The outcome of any surgical attack on an intracranial tumor depends on the cell type of the lesion and its position within the skull. Tumors composed of glial elements, the true brain tumors, have a much poorer prognosis than lesions with basic cell types that are fibroblastic, glandular, or vascular in origin. Tumors composed of these three types might well be termed intracranial rather than brain tumors, since their cell types are not those of the brain itself. Glial tumors tend to infiltrate the brain to a varying extent, and, for this reason, total extirpation is frequently impossible. Furthermore, since these tumors are invasive, the neurological deficits they produce are due to permanent brain damage and may persist even after the tumor has been extirpated. Nonglial tumors, on the other hand, do not invade the brain but force it to one side. A line of cleavage always exists between such lesions and the brain, total extirpation is possible, and, since neurological deficits are caused by brain compression rather than invasion, such deficits may completely disappear after removal of the tumor.

The position of a lesion largely determines the success or failure of surgical removal. Tumors of the convexities of the brain are more accessible than tumors in the subfrontal or subtentorial regions. A meningioma of the inner end of the sphenoid ridge, closely involved with the carotid artery, or a perineurial fibroblastoma in the cerebellopontine angle, adherent to the brain stem and extending upward through the incisura, (although both are tumors that may be totally extirpated when found in other regions) may become, because of its position, as impossible to remove completely as a glioblastic tumor of the convexity of the brain. On the other hand, a relatively benign glioblastic tumor involving the tip of the frontal, temporal, or occipital lobe may be entirely eradicated by removal of the lobe.

Finally, the stage at which diagnosis of a brain tumor is made may influence the result of surgery. Here again, the position of the lesion is important. Tumors that involve active areas of the brain such as the motor cortex, causing convulsions or paralysis; the optic radiations, producing visual field defects; or the cerebellar hemispheres, with changes in equilibrium; because of these symptoms, call prompt attention to the brain as the site of the lesion. But tumors in silent brain areas, such as the frontal lobes, the right temporal lobe, in the midline above or below the tentorium, may produce no clinical findings that can be related in any way to the brain. Intermittent headache and vomiting may be the only symptoms, and they can be due to many causes other than brain tumor. When visual loss, progressive headache, and uncontrollable vomiting appear, an intracranial lesion is first suspected. The neurosurgeon at times wonders why the attending physician was so late in reaching a diagnosis. The reason is, of course, that the antecedent symptoms were nonspecific. The alert physician naturally considers first the more common causes for a patient's complaints, and only when repeated and thorough examinations have ruled these out or when new symptoms appear suggesting an intracranial complication does he consider a less common lesion, such as a brain tumor. Consequently, brain tumors often are not diagnosed while they are still in a stage that might make total extirpation reasonably easy.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Session of the American Medical Association, New York, June 2, 1953.

In addition, as the tumor expands and causes increased intracranial pressure the general condition of the patient deteriorates until he is a poor surgical risk.

After it has been established that an intracranial mass lesion is the probable cause of a clinical picture, localization of the tumor is not difficult. With modern roentgenographic technique and ventriculography or arteriography, 95% of all intracranial mass lesions can be accurately localized.

Further, brain tumors can be divided into five groups; glial cell tumors, fibroblastic tumors, glandular tumors, which are preponderantly pituitary, vascular tumors, and a mixed group of metastatic, congenital, and other tumors of many different types that occur much less frequently than the four larger groups.

SURVEY OF CASES

A survey has been made of 1,733 cases of verified brain tumor seen on the neurosurgical service of the Hospital of the University of Pennsylvania from Jan. 1, 1930, to Jan. 1, 1950. These tumors have been classified in the five groups, according to their pathology, in an attempt to learn the prognosis and length of surgical survival in each group. In these 1,733 cases, 496 operative and 130 nonoperative deaths occurred, a case mortality of 36%. Among the 1,603 patients who had surgery, 1,926 operative procedures were performed, with 496 postoperative deaths, an operative mortality of 25%. As of Jan. 1, 1953, 409 patients, or 25%, were living; 47 had survived 20 years or more. In addition, 48 patients lived 10 years or over; 77 lived 5 to 10 years; and 573 survived surgery less than 5 years. Among the 48 patients who lived 10 years or more 3 finally died of recurrence, and among those who lived 5 to 10 years the tumor recurred fatally in 49 instances.

Review of the tumor types among the 534 patients who lived for five years or over shows clearly the importance of this factor in prognosis (see table). There were 203 fibroblastic tumors, the meningiomas and acoustic neuromas; 127 glandular lesions of pituitary origin; 84 gliomas, all of the slow-growing astrocytoma fibrillare or oligodendroglioma type; and 36 tumors of blood vessel origin. The remaining 84 tumors were divided among many subgroups. No patient with a glioblastoma multiforme or a malignant metastasis to the brain, from the lungs or elsewhere, survived over five years. Most of the patients died within three years.

Cell Type of Tumors in 534 Patients Who Survived Five Years or More After Surgery

	No. of Patients	%
Fibroblastic (meningiomas and acoustic neuromas)..	203	39
Glandular (pituitary adenomas)......................	127	22
Gliomatous (astrocytomas)	84	16
Vascular (hemangiomas)	36	7
Miscellaneous types	84	16

The astrocytomas total 348 cases, or 20% of the entire series. Of these, 218 were cerebral and 130, cerebellar. The division of this group according to position of the tumor above or below the tentorium is necessary because of the apparent difference in life expectancy with the two types. Among the 218 patients with cerebral astrocytomas, 27, or 12%, are still alive. Of the 130 with cerebellar astrocytomas, 45, or 35%, are alive in 1953.

Of the 45 living patients who had cerebellar astrocytomas, 36 had cystic and 9, solid tumors. Survival was prolonged when the tumor nodule was removed from the cyst wall. The nine solid tumors lay laterally in the cerebellar hemisphere, so that complete removal was possible. No patient with a solid glioma of the vermis cerebelli lived over five years. In two additional cases of cerebellar astrocytoma, one solid and one cystic, the patients survived for 11 years and died of recurrence. Of the 47 patients with cerebellar glioma who survived beyond 10 years, 41 were able to return to work.

In the 27 patients with cerebral astrocytomas who are still alive, the tumors were located as follows: nine temporal, eight parietal, six frontal, and four occipital; all but five were in the right cerebral hemisphere in right-handed patients. Extensive resections were done, with apparently complete removal in all but one case. In this instance there was a recurrence of a cystic astrocytoma in the right parietal region after 16 years. The patient was operated on again and has been well and working ever since. Five additional patients with cerebral glioma lived over 10 years and died of intercurrent disease. Five others lived over five years; four died from recurrence and one, in an accident. In this group of 37 patients who lived five years or more, 25 returned to work.

Glial tumors, the true brain tumors, have a much more unfavorable prognosis than lesions composed of nonglial elements, the intracranial tumors. A glioma must be favorably situated within the cranial cavity and must have a highly specialized and slow-growing cell type, such as an astrocyte or an oligodendroglia, as its basic component to make complete extirpation possible or to assure a reasonable life expectancy after partial removal. All the fibroblastic tumors, regardless of location, should be vigorously attacked and every reasonable risk taken to accomplish complete removal. The position of the tumor and its accessibility determine the outcome of surgery. Pituitary adenomas respond well to intracapsular, subtotal extirpation with roentgen ray therapy. Vascular tumors, so commonly found in the cerebellum and almost always cystic, can be cured if the tumor nodule in the cyst wall is removed.

SUMMARY AND CONCLUSIONS

Results of intracranial surgery for tumors compare favorably with results of tumor removal in general. In this group of 1,733 patients, 534, or 30% lived five years or more after operation. Of the 1,733 patients, 626 died either before or shortly after operation, leaving 1,107 patients who could be followed up. In this group, 573 had lesions that were either rapidly recurring gliomas or metastatic carcinoma; none of these patients lived over five years, few over three years. If this unfavorable group is eliminated, 534 cases of tumors with better prognosis remain. All of these 534 patients, or roughly 49% of the 1,107 patients who were followed, lived five years or more, and 409 of them, or 35%, are still living, 4 to 23 years after surgery.

The skill and experience of the surgeon are vital in removal of a brain tumor; however, all his skill and experience are of no avail unless a tumor is relatively benign and is in an accessible position.

CLINICAL EVALUATION OF DEXTRAN AS A PLASMA VOLUME EXPANDER

Harry W. Bowman, M.D., Bethlehem, Pa.

At the termination of World War II, the advent of atomic destruction alerted the medical profession to the great need for emergency stockpiling of plasma and plasma substitutes. At present, three plasma substitutes are widely used, dextran, polyvinylpyrrolidone, and oxypolygelatin. "Plasma volume expander" is the accepted name for these materials, since there is no true substitute for plasma or whole blood. Plasma expanders may be divided into four groups: (1) Blood derivatives: albumin, plasma, and modified globin; (2) modified proteins: gelatin and oxypolygelatin; (3) polymerized carbohydrates: dextran; (4) plastics: polyvinylpyrrolidone.[1a]

My clinical experience with plasma volume expanders has been limited almost entirely to the evaluation of dextran. I have had very little experience with polyvinylpyrrolidone, and I have not used oxypolygelatin in any of my studies.

METHOD AND MATERIALS

I have administered more than 500 infusions of dextran (Plavolex), in 6% isotonic sodium chloride solution during an 18 month period. The first 76 infusions were studied under the protocol established by the National Research Council. Plasma volume, blood volume, hematocrit, and excretion studies were done on each of the original 76 patients before and after administration of 500 cc. of dextran solution. The temperature, pulse rate, respiratory rate, blood pressure, skin reaction and temperature, and orientation of each patient were recorded during all dextran infusions. Unfavorable reactions occurred in two patients. These were characterized by itching, mild urticaria, severe chills, and a temperature rise to 103 F. These symptoms are typical of reactions to dextran but the reactions are easily controlled with the use of antipyretics and sedation. All of my original clinical studies were done on patients who were not receiving any drug therapy or who had completely recovered from anesthesia. The age group ranged from 18 to 60, and no patient had a chronic or an acute infection.

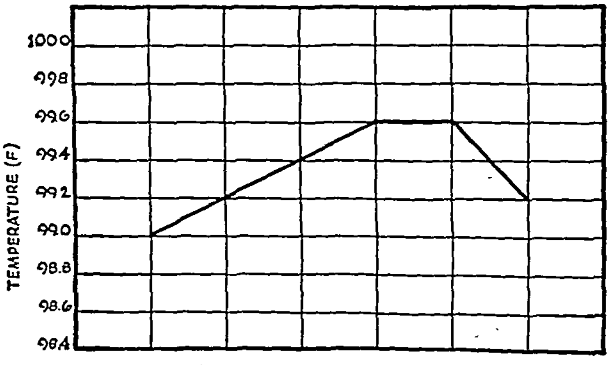

Fig. 1.—Average oral temperature among 76 patients before and during the 24 hour period following infusion of dextran solution.

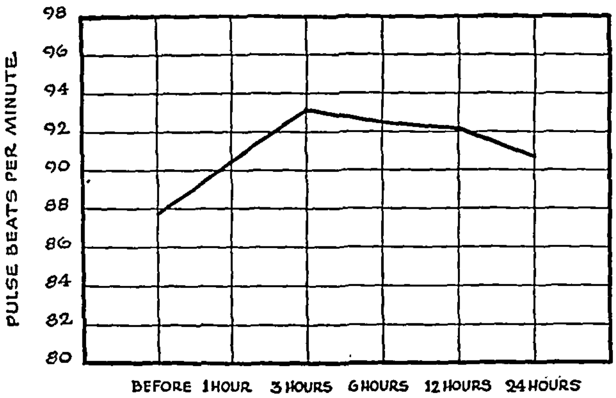

Fig. 2.—Average pulse rate among 76 patients before and during the 24 hour period following infusion of dextran solution.

Dextran is a polysaccharide, or polymer of glucose, manufactured from sucrose by a fermentation process. The coccus Leuconostoc mesenteroides produces an exocellular enzyme, which polymerizes glucose into a polysaccharide, forming the end product dextran. The molecular weight of dextran varies from 50,000 to 100,000, averaging 65,000 to 70,000, and approximates that of human plasma.

CLINICAL EFFECTS OF DEXTRAN INFUSION

Figure 1 shows that the average oral temperature rise after intravenous administration of dextran is not more than 0.8 F. Part of the temperature rise is probably due to postsurgical tissue reaction. The average pulse rate ranged from 86 to 94 beats per minute, which can be considered within normal limits. Figure 2 shows the radial pulse variations.

Other investigators [1] have shown the average increase in cardiac output after infusion of 500 cc. of dextran to be 30%. The cardiac stroke volume, peripheral venous pressure, right auricular pressure, and pulmonary capillary pressure are increased. A change of this nature is to be expected after a sudden increase in plasma volume. Figure 3 shows the average blood pressure changes after a single infusion of dextran. A rise in systolic pressure and a corresponding decrease in diastolic pressure reached the maximum at the third hour after administration of dextran. The clinical findings represented graphically correspond with physiological changes in cardiac activity.

Plasma volume and total blood volume studies have been of great interest. Figure 4 illustrates the average increase in plasma volume and in blood volume after an infusion of 500 cc. of dextran. The average plasma volume increase was 450 cc., and the average blood volume

[1] Symposium on Plasma Volume Expanders in the Treatment of Shock, A. M. A. Arch. Surg. 63: 718-749 (Dec.) 1951.

increase was 550 cc. The response to dextran, as indicated by these figures, has been most gratifying to both the surgeon and the anesthesiologist, particularly in the treatment of burns, traumatic shock, and surgical shock.

Figure 5 shows the average concentration of dextran in the plasma before and at intervals after infusion. A rapid rise of the dextran level to 750 mg. per 100 cc. is noted in the first hour after infusion of one unit. At the end of the first hour the level begins to fall gradually and continues to fall during the next 24 hours. This graphic representation illustrates dextran's valuable prolonged effect in maintaining plasma volume increase and its value in the emergency fluid treatment of shock.

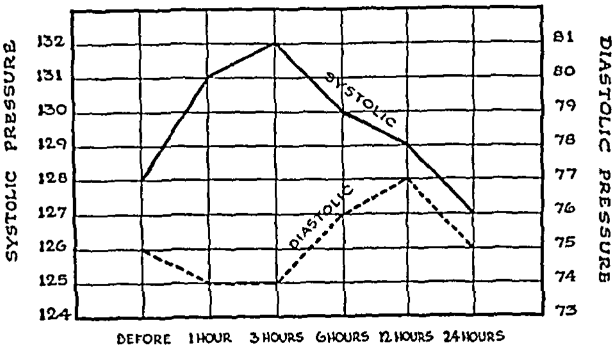

Fig. 3.—Average systolic and diastolic blood pressures among 76 patients before and during the 24 hour period following infusion of dextran solution.

Infusion of dextran was always preceded and followed by hematocrit studies. Figure 6 shows the hemodilution effect of dextran. The hematocrit fell from a normal level to a level of 39.2% during the first hour and gradually returned toward the normal level in the ensuing 24 hours. Although the drop in hematocrit was not serious, I believe this response is an indication that the use of whole blood is essential in traumatic or surgical shock.

Data released by the National Research Council indicate that in animals 93% of intravenously administered dextran is accounted for in the urine and in expired air within a 10 day period; 7% is probably metabolized in the body.[2] I believe that dextran is excreted and metabolized in humans in a corresponding manner. Excretion of 32.9% over a 24 hour period has occurred in my series. The excretion levels fall well within the limits required of a satisfactory plasma volume expander, as indicated in figure 7.

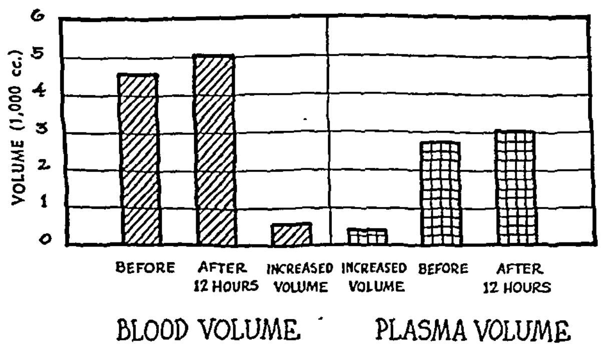

Fig. 4.—Average blood and plasma volumes among 76 patients before and 12 hours after infusion of dextran solution.

COMPARISON WITH OTHER PLASMA VOLUME EXPANDERS

My experience with polyvinylpyrrolidone has been limited; however, the clinical results from its use compare favorably with results from the use of dextran. Histological changes in certain body tissues are known to occur after infusion of polyvinylpyrrolidone, but I have not noted such changes after use of dextran. I have been impressed also by the evidence that dextran has interfered in no way with blood typing or cross matching in over 500 infusions. Dextran appears to be superior to oxypolygelatin, serum albumin, and plasma in its effect on plasma volume expansion. The table shows the comparative effects on plasma volume expansion of the four materials. The figures point to a prolonged satisfactory response with dextran. The remaining three substances fall short in the production of prolonged effect on plasma volume.

During the past six months, I have been successful in the clinical use of dextran combined with modified human globin. Modified human globin is the protein extract of red blood cells. It is packaged in the dehydrated form and is not readily soluble in dextran; however, it is soluble in 5% dextrose and water, and the resultant solution has the appearance of plasma. I have administered the globin preparation simultaneously with dextran, with good results. My work with this combination has been limited, and I cannot report on a convincing series of patients, but I can state that the patients have been safely supplied with a protein-rich solution plus a plasma volume increase. This form of intravenous therapy is extremely valuable in the treatment of burns, because of the osmotic and oncotic pressure effect and the protein intake. I have noted improved postoperative wound healing, particularly in the emaciated patient. This experience points to the possibly great therapeutic value of modified human globin and dextran in the treatment of the severely burned patient as well as the emaciated, undernourished patient and possibly in the postoperative care of the surgically treated patient. More extensive studies are being carried out at present with a combination of these two materials.

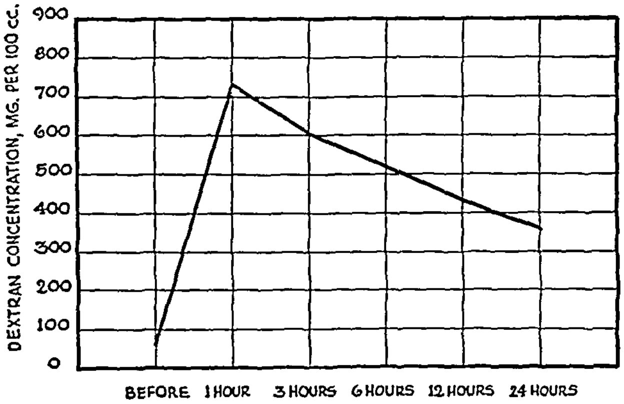

Fig. 5.—Average plasma concentration of dextran among 76 patients before and during the 24 hour period following dextran infusion.

COMMENT

I believe that dextran meets all the clinical requirements of a satisfactory plasma volume expander for the following reasons. 1. It rarely produces untoward reactions. 2. It does not cause antigenicity. 3. It is not retained for any significant period in the body and does not cause histological changes within the tissues. 4. It does not interfere with blood typing and cross matching. 5. It produces satisfactory blood volume expansion, as indicated by plasma volume and blood volume studies. 6. It is immediately available for administration and can be stored at any temperature above the freezing point.

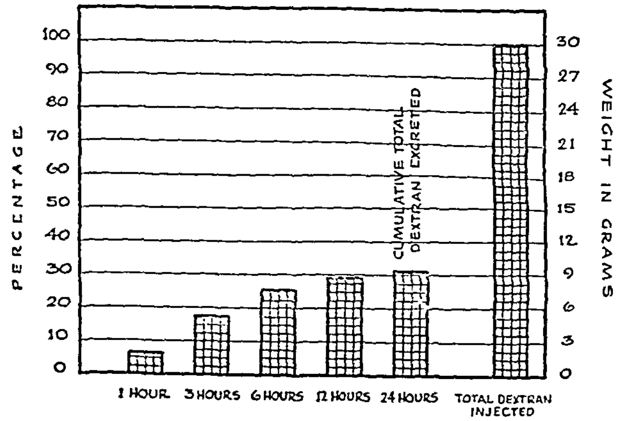

Fig. 7.—Average dextran excretion among 76 patients over the 24 hour period following its injection.

Space does not permit a detailed discussion of the many dramatic results obtained with the use of dextran in treatment for burns, traumatic shock, anuria, cerebral edema, postsurgical edema of the gastrointestinal tract, and pulmonary edema. I believe, however, that concentrations of 10% and 20% salt-free dextran will be of greater value, particularly in the treatment of burns and edema.

SUMMARY AND CONCLUSIONS

The results of clinical and laboratory studies of dextran are reported and prove, I believe, the great value of this material as a plasma volume expander. Studies in progress on the combined use of dextran and modified human globin are mentioned. I do not believe that polyvinylpyrrolidone or oxypolygelatin can be overlooked as potentially satisfactory plasma expanders, although at present their clinical administration is attended by some difficulty. Finally, plasma volume expanders are not, and probably never will be, satisfactory substitutes for whole blood. Whole blood is essential for the maintenance of normal human physiological function.

CLINICAL NOTES

NALORPHINE (NALLINE) ANTAGONISM TO RACEMORPHAN (DROMORAN) INTOXICATION

Edward F. Domino, M.D.
Edward W. Pelikan, M.D.
and
Eugene F. Traut, M.D., Chicago

Experiments with laboratory animals indicate that nalorphine (Nalline) is effective in antagonizing most of the effects of morphine,[1] codeine, dihydromorphinone (Dilaudid), metopon, methadone,[2] and meperidine (Demerol).[3] Successful clinical use of nalorphine to antagonize the respiratory depression caused by morphine, dihydromorphinone, methadone, and meperidine has been reported.[4] Chase, Boyd, and Andrews have

reported successful treatment of dihydromorphinone and racemorphan poisoning with nalorphine.[5] We have had the opportunity to confirm the dramatic efficacy of nalorphine in another case of racemorphan intoxication. The unusual circumstances involved in this case permit the drawing of certain conclusions concerning the pharmacological activity of both racemorphan and nalorphine.

REPORT OF A CASE

A 54-year-old white woman entered the hospital in December, 1952, because of generalized carcinomatosis. Six months previously she had been treated for carcinoma of the uterus with radium implants and subsequent total hysterectomy. For a month prior to admission she had been bedridden and had complained of severe pain in the back and left hip, with "knife-like" radiation of pain down both legs. Physical examination on admission showed only severe muscular atrophy in both legs, which were held flexed and adducted, and a Gonda reflex on the left. Roentgenologic examination revealed a pathological fracture of the left femur, with bone changes suggestive of metastases in the inferior ramus of the right pubis. Since there was no papilledema, a lumbar puncture was performed, the results of which were within normal limits, except for an elevated spinal fluid pressure (340 mm. of cerebrospinal fluid). Results of routine hematological and urine analyses were within normal limits.

Five milligrams of racemorphan was given subcutaneously at 9 p. m. to control pain. Throughout the night the patient rested well but was slightly disoriented. Another lumbar puncture was done the following morning, which showed a pressure of 290 mm. of cerebrospinal fluid. At 1:30 p. m. on the second day, the patient again complained of hip and leg pain and was given another 5 mg. of racemorphan subcutaneously. She promptly went to sleep. Two hours later it was noted that she could not be aroused and had Biot respiration at a rate of nine per minute. She continued to be semicomatose for 10 hours. At 12:15 a. m., she responded only to painful stimuli. The left patellar reflex was diminished, but a Gonda reflex was present on the left. The eyes were immobile, and the pupils were greatly dilated and unresponsive to light; the corneal reflex was barely perceptible. Biot respiration continued at a rate of nine per minute, and the patient had periods of apnea lasting 15 seconds.

Five milligrams of nalorphine was given intramuscularly at 12:25 a. m. By 12:30 a. m., the depth of respiration had increased, and the periods of apnea were shortened to 10 seconds. At 12:40 a. m., respiration was regular and of normal amplitude, with a rate of 14 to 16 per minute. The patient opened her eyes at 1 a. m. and said spontaneously, "I'm waking up now." Fifteen minutes later respiration was regular at 18 per minute. The corneal reflex was present, and the pupils reacted sluggishly to light. The patient was alert and rational. Eighty minutes after the administration of nalorphine the patient complained of severe pain.

Results of liver and kidney function tests were as follows: serum alkaline phosphatase level, 13.2 units per 100 cc.; sulfobromophthalein (Bromsulphalein) sodium test, 45.6% retention after 45 minutes; nonprotein nitrogen level, 34 mg. per 100 cc. The urine had a specific gravity of 1.024 and contained neither protein nor reducing substances. A test for urinary urobilinogen (Watson qualitative method) was positive in 1:100 dilution.

Three days later 2.5 mg. of racemorphan administered subcutaneously caused the patient to become generally depressed; Biot respiration returned at a rate of 10 to 12 per minute, with 20 second periods of apnea. The administration of 2.5 mg. of nalorphine intramuscularly reduced the duration of apnea from 20 to 17 seconds and increased the depth of respiration. It also made the patient more alert and mindful of her pain. Subsequently, the patient's pain was adequately controlled without ill effects by administration occasionally of small doses (4 mg.) of morphine. The possibility that the hypodermic injections had a suggestive effect was ruled out by injections of sterile saline solution, which were totally ineffective.

COMMENT

Signs of severe narcotic poisoning (decreased respiratory rate and altered respiratory rhythm, depressed corneal reflexes, and fixed and dilated pupils) persisted in this patient for at least 12 hours after the administration of racemorphan (two doses of 5 mg. each given 15 hours apart). Such a prolonged and cumulative action is best explained as the result of a diminished rate of detoxification of racemorphan. The apparently normal kidney function and severe hepatic damage present in this patient suggest that the liver is the major site of detoxification of racemorphan, as it is for morphine.[6] Thus, racemorphan, like opium or its derivatives, should be used with caution in persons with diminished liver function. The degree to which probable brain damage and an elevated cerebrospinal fluid pressure enhanced the action of racemorphan is difficult to evaluate. Nevertheless, the results observed emphasize the need for caution in administration of narcotics to patients with increased intracranial pressure.

In the case reported, nalorphine promptly antagonized several effects of racemorphan. Respiratory depression was reversed within 15 minutes after the intramuscular injection of 5 mg. of nalorphine, as evidenced by an increased depth and rate of respiration and the conversion of respiration from Biot to normal regular rhythm. The analgesic and general depressant effects of racemorphan were also counteracted. Presumably, analgesia, respiratory depression, and dulling of consciousness are not manifestations of fundamentally different pharmacodynamic actions of racemorphan.

SUMMARY AND CONCLUSIONS

A patient with racemorphan (Dromoran) poisoning successfully treated with nalorphine (Nalline) is described. Of all the observed effects of racemorphan, antagonism to respiratory depression occurred most quickly. Racemorphan should be used with caution in patients with severe liver damage, since the liver is probably the major site of detoxification of this substance.

ADDENDUM

After this manuscript had been prepared for publication, Bornstein and co-workers [7] reported two more cases of successful treatment of racemorphan poisoning with nalorphine.

Use of Radioisotopes.—There are about 10 radioisotopes which can be produced with sufficiently high specific activity not only to supplant radium but to challenge the pre-eminence of therapeutic x-ray equipment. Three of these isotopes, Cesium^{137}, Europium^{152}, and Cobalt^{60}, can be designed into machines which have many advantages over an electrical device of similar energy.—M. Brucer, M.D., Encouraging and Discouraging Research with Therapeutic Radioisotopes, *Journal of Kentucky State Medical Association,* June, 1953.

CYCLIC NEUTROPENIA

REPORT OF A CASE TREATED BY SPLENECTOMY

William D. Coventry, M.D., Duluth, Minn.

Cyclic neutropenia, or periodic neutropenia as Reimann [1] has recently termed it, is a rare hematological disorder of unknown etiology and is characterized by severe neutropenia or agranulocytosis recurring at approximately 21 day intervals. The neutropenic phase, which lasts for from five to eight days, is usually accompanied by mild fever and localized, superficial infections of the skin or mucous membranes. Sometimes the infection is so severe that it simulates acute agranulocytosis, while, at other times, infection may be minimal or even absent. These symptoms always subside as the neutrophils rise to normal levels during the recovery periods. This sequence of events continues for years without impairing the general health of the person. Accurate recognition of this type of neutropenia is of great importance because it implies a favorable prognosis and because the disorder must be differentiated from acute and chronic types of neutropenia, both idiopathic and secondary, in which a serious outcome may be expected.

Leale,[2] in 1910, first described this disorder in a 3½-year-old infant. In 1946, Vahlquist [3] reviewed the literature and described the disorder in one of his own patients, an infant. He suggested that the disease be considered an entity. This was also the opinion of Reimann,[1] who, in 1949, collected 16 cases from the literature and suggested that this entity be included in his group of periodic diseases. Recently both Sandella [4] and Monto [5] have described this disorder in an older person. The few deaths so far reported have been from unrelated causes. In order to elucidate further the clinical features of this rare and benign type of neutropenia, another case, treated by splenectomy, is described.

REPORT OF A CASE

A married girl, 16 years of age, was first seen in October, 1948, and remained under observation until October, 1952. In October, 1948, she was admitted to the dermatology service of the hospital because, for the preceding four days, she had had a severe furunculosis that involved the buttocks and groin and that was accompanied by fever and chills. Three weeks before she had delivered a normal male infant. No leukocyte counts were obtained at that time, but, during pregnancy, several blood cell counts had shown neutropenia. She recalled that during pregnancy she had not had any skin or mucous membrane infections but that before, for as long as she could remember, she had had repeated superficial infections of the skin and mouth.

Physical examination revealed a well-nourished and well-developed young girl who showed no abnormality except for mild gingivitis and several large furuncles of the buttocks and groin. Multiple scars from previous similar infections were also present on the buttocks. The temperature was 104 F. The hemoglobin level was 9.7 gm. per 100 cc.; erythrocytes, 3,400,000; and leukocytes, 3,850 per cubic millimeter, with 11% neutrophils, 2% eosinophils, 1% basophils, 26% monocytes, and 60% lymphocytes. The number of platelets appeared to be increased on the blood film. Urinalysis was normal. Blood cultures showed no growth. A chest film was normal. There was a strongly positive reaction to intradermal Staphylococcus toxoid in 1:100 solution. Treatment with Staphylococcus toxoid, transfusions, and antibiotics was followed by a prompt drop in temperature and rapid healing of all lesions. Three days after admission, the number of neutrophils had reached 38%, and, at the time of discharge from the hospital on the 11th day, there were 6,050 leukocytes, with 60% neutrophils, 1% eosinophils, no basophils, 35% lymphocytes, and 4% monocytes, a normal distribution.

Sternal marrow aspiration was performed after the blood cell values had returned to normal. The myelogram (cell type percentage in 400 nucleated cells) revealed myeloblasts, 1.25%; leukoblasts, 1%; promyelocytes, 1.25%; myelocytes (neutrophils), 8%; myelocytes (eosinophils), 0.75%; myelocytes (basophils), 0.5%; metamyelocytes, 15.75%; neutrophils, 25%; eosinophils, 3.5%; basophils, 2.25%; lymphocytes, 19%; monocytes, 5%; erythroblasts, 0.25%; normoblasts (basophils), 2.5%; and normoblasts, 16.75%. Megakaryocytes were not estimated. This was considered to be a normal marrow specimen and corresponds to the figures given by Fullerton and Duguid [6] for the remission phase.

The patient's medical history was obtained from her family physician. Records made at the time of her birth on April 25, 1932, showed that parturition was normal. No blood cell counts were obtained at that time. In March, 1933, when the patient was one year old, otitis media with mastoiditis, multiple furuncles, and anal fissure occurred. Mastoidectomy, adenoidectomy, and cauterization of the fissure were done with uncomplicated recovery. Neutropenia and anemia were first noted during this illness.

Between March, 1933, and October, 1948, the girl was hospitalized on many occasions for treatment of recurrent infections. Ulcerative stomatitis and gingivitis were first noted in August, 1933, and this condition recurred continually throughout her life; several dental extractions were done in an attempt to cure it. During this period, at one time or another, furuncles or abscesses involving the fingers, toes, axillas, buttocks, elbows, conjunctivas, and ears were present. These infections always healed without serious complications. Laboratory records showed that anemia, leukopenia, and neutropenia occurred at various times. No detailed serial blood studies were performed during this 15 year period. The girl's father, mother, and two siblings had always been in good health. None had a history of infections or neutropenia. The only history of allergy in the patient or her family was urticaria on one occasion following a penicillin injection. No time relationship existed between the menses and the phase of neutropenia. The patient was well adjusted to her illness and showed no neurotic tendencies.

She was admitted to the hospital again in February, 1949, because of a small ulcer on the left buccal mucosa and pyoderma on the right thumb of six days' duration. The temperature was 100.6 F. The hemoglobin level was 13.5 gm. per 100 cc.; erythrocytes, 4,100,000; and leukocytes, 5,300 per cubic millimeter, with neutrophils, 42%; eosinophils, 20%; basophils, 1%; lymphocytes, 31%; and monocytes, 6%. Findings on physical examination were normal except for the local lesions. The spleen was not palpable. There was no enlargement of lymph nodes. Recovery was rapid with antibiotic and local treatment. One week after the patient left the hospital, the leukocyte count was 5,600 per cubic millimeter, and the differential count was normal.

A third hospital admission was necessary in April, 1949, because of purulent gingivitis, with severe regional lymphad-

enitis of five days' duration. The temperature was 102 F. The hemoglobin level was 11 gm. per 100 cc.; erythrocytes, 4,600,000; and leukocytes, 5,000 per cubic millimeter, with neutrophils, 10%, eosinophils, 5%, lymphocytes, 45%, and monocytes, 40%. Again clinical improvement was rapid. During the next 10 months, the patient experienced repeated mild episodes of bleeding gingivitis and single buccal ulcers. There was slight elevation of temperature during these episodes, but the girl was able to continue with her routine of life and no hospital treatment was necessary. Many leukocyte counts taken during this period ranged from 2,800 to 5,400 cells per cubic millimeter and averaged about 4,000. Sometimes neutrophils were absent for four or five successive days. On other occasions, the number of neutrophils reached 46%. Complete hematological studies revealed no other abnormality.

Reference to the recently published paper by Reimann and de Berardinis[1] in which the entity periodic (cyclic) neutropenia was described suggested this as the probable diagnosis. During March and April, 1950, therefore, serial leukocyte and differential counts were done as nearly at daily intervals as possible. The results of this survey in terms of total neutrophils per cubic millimeter are shown in the table. Neutropenia lasting 5 to 8 days recurred regularly, with a recovery interval of approximately 12 to 14 days between each phase. Each cycle, with its phase of recovery and agranulocytosis, totaled 18 to 21 days. The diagnosis of cyclic neutropenia was thus established.

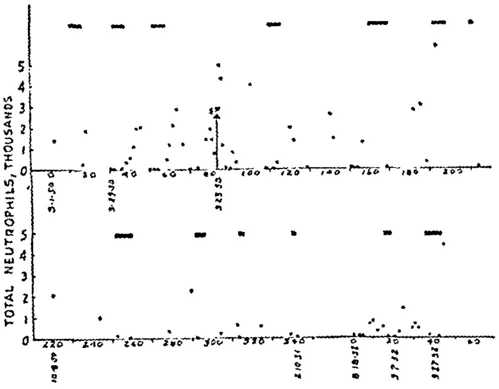
Treatment up to this time had consisted of good oral and skin hygiene for the prevention of infection, with the use of antibiotics when these episodes became severer. In view of the cases reported by Doan[7] and Fullerton and Duguid,[6] in which splenectomy was followed by relief of symptoms, it was decided that this procedure offered the patient the greatest hope for permanent improvement. On May 23, 1950, during a period of remission, splenectomy was performed. The postoperative course was uneventful, and the patient was discharged on the ninth hospital day. The pathologist's report stated that the specimen consisted of a spleen weighing 280 gm. The capsule was somewhat tense, and, on cut section, the tissue had a markedly congested and suggestive beefy-like appearance. There was no evidence of infarction, and the follicles were not at all prominent on gross examination. The pedicle was not unusual. On microscopic examination there was grade 2 neutrophilic infiltration of the splenic sinuses that was not accompanied by the usual congestion of sinuses found in toxic splenitis of the same grade. No unusual phagocytosis of these neutrophils was found. There was no unusual abnormality. The findings were consistent with the diagnosis of periodic neutropenia.

The immediate response to splenectomy by the leukocytes was a sharp rise in the number of white blood cells to a maximum level of 16,000 per cubic millimeter, with 87% neutrophils. By the third postoperative day, however, a reversion to previous levels had begun, and, subsequently, the next regular 21 day exacerbation of neutropenia occurred with the usual attendant gingivitis. For the next nine months, the patient was observed frequently, and cycles of neutropenia similar in degree to those noted before splenectomy recurred at the usual intervals. In the remission phase, however, the neutrophils often reached heights exceeding the presplenectomy levels. This was in part due to a permanent postsplenectomy rise in the average total leukocyte count (see figure). In spite of this, however, periodic infections continued to recur as the cycles of agranulocytosis continued unabated. In September, 1952, two years and four months after splenectomy, a survey of the neutropenic cycle was again made, and it was found to recur at precisely the same interval as before splenectomy (see figure).

Infections of moderate severity recurred regularly during the nine month period from May, 1950, to February, 1951, and hospitalization was necessary on one occasion. Several neutropenic periods were asymptomatic. A second pregnancy occurred in May, 1951, and, in July, the patient was admitted to the hospital during a neutropenic phase, with pyelitis of pregnancy. Recovery was rapid as usual. Except for this incident, there was no infection during the second pregnancy. A normal parturition took place in December, 1951, during a neutropenic phase and was without complication or infection of any kind. The infant was a healthy male. Four consecutive leukocyte counts done on the infant at the age of two months, over a period of 20 days, showed an average of 9,500 white blood cells per cubic millimeter, with neutrophils, 33%; eosinophils, 3%; lymphocytes, 60%; and monocytes, 14%, a normal differential count for an infant of this age. The first postpartum cycle of neutropenia in the mother was again accompanied by severe furunculosis, this time of the vulva. During the next nine months, there was no periodic infection; however, when last observed, in October, 1952, two recent successive cycles had been accompanied by moderate gingivitis with lymphadenitis and severe pharyngitis, respectively. Several severer attacks have occurred subsequently.

COMMENT

The cause of this rare disorder of the neutrophils is obscure. A congenital etiology is suggested by the 19 cases,[8] including the present one, reported in the literature in which about half had a definite history of onset in infancy. Regardless of the time of onset, however, the diagnosis may be made at any age. Two recent cases have been described in persons 64[1] and 78[5] years of age. Hereditary factors have not been adequately studied. In the case herein reported, they appear to be ruled out by the absence of neutropenia in both parents, siblings, and one child.



Periods of neutropenia, infection (rectangles), and total leukocyte counts in patient before and after splenectomy *(SP)*.

The mechanism by which the neutrophils periodically disappear from the blood remains equally obscure. By repeated marrow aspirations, Fullerton and Duguid[6] found that, in the neutropenic phase, not only neutrophils are reduced but also myelocytes and myeloblasts; thus, the entire myelocytic series is depressed. These authors conclude that the process is not a maturation defect or arrest. Sandella,[4] on the other hand, on the basis of multiple marrow aspirations, believes that depression and maturation arrest at the promyelocytic-myelocytic level are present during the neutropenic phase. Kline,[9] who has recently studied the life span of leukocytes, is unable to explain the sudden fall in the number of neutrophils by a cessation of cell production. He suggests excessive destruction of these cells as a more likely explanation. Periodic sequestration of the neutrophils also must

be considered. The epinephrine test was done on this patient in periods of both remission and exacerbation in order to evaluate this possibility, but, in each instance, although a definite leukocytosis resulted, there was no increase in the absolute number of neutrophils.

Treatment with various hematinic drugs, hormones, antibiotics, vitamins, antiallergic drugs, and vaccines has so far failed to alter the cyclic changes in the neutrophils. Recently Monto and associates [5] described the use of corticotropin (ACTH) during the neutropenic phase. Seventy-two hours after this therapy was begun, the leukocyte count increased from 600, with almost complete agranulocytosis, to 1,650 per cubic millimeter, with 67% neutrophils and coincident clinical improvement. Reimann, however, after administering a single test dose of 25 mg. of adrenocorticotrophic hormone during an episode of neutropenia, noted a fall in total number of leukocytes from 4,000 to 2,000 per cubic millimeter and a further decrease in the number of neutrophils. In view of these conflicting results, it would appear that corticotropin should be tried in consecutive cycles of neutropenia before conclusions as to its value are reached. The effect of any treatment given during a single neutropenic cycle must be evaluated with regard to the spontaneous increase in neutrophils that always follows.

Splenectomy for the treatment of cyclic neutropenia appears to have first been performed in Doan's case.[7] His patient had both congenital hemolytic icterus and cyclic neutropenia. After removal of the spleen, the anemia was completely relieved, as expected; but in addition, the leukocyte count was raised from a low of 1,000 or less per cubic millimeter in the neutropenic phase to a level of 5,000. This permitted the patient to carry on her work in reasonably good health after many years of disability from recurrent infections. The regular cycles of neutropenia were unaffected. Up to the present, eight cases [10] similarly treated have been reported in the literature, including this case. In four of these,[11] substantial to complete relief from periodic infections resulted. Significantly, in each instance, the spleen was considerably enlarged: three to four times normal size, 500 gm., 670 gm., and 520 gm., respectively. The corresponding ages of these patients were 62, 18, 64, and 78 years. The remainder, including this case, continued to have periodic infections of a degree that indicated doubtful or no benefit from splenectomy. In this group, the spleen was normal or only slightly increased in size: 165 gm., 17 by 10.5 cm., 160 gm., and, in this case, 280 gm. The corresponding ages were 18, 23, 24, and 18 years, respectively. From this it appears that (1) splenectomy will be beneficial if the spleen is considerably enlarged, especially in an elderly patient, and (2) improvement should not be expected in young patients with a normal or slightly enlarged spleen. All patients have survived the operation without complications. Owen's patient died one year later from pneumonia. In Sandella's patient, death from lymphosarcoma occurred 16 months after splenectomy.

My patient has now been observed for two and a half years since splenectomy. During the first half of this period, the infections continued at regular intervals and their severity was unchanged. During pregnancy, infections were absent. During 1952, there were no significant infections for a period of nine months, but, during the remaining months, several severe attacks have occurred. Good hygiene and the early use of antibiotics have been helpful in controlling the episodes. Splenectomy may have had some palliative influence on the severity of the infections, yet incapacitating attacks have continued to occur in spite of the operation.

As to effects on the blood, removal of the spleen in the case described did not change the degree or periodicity of the neutropenic cycle, but it was followed by a rise in the average total leukocyte count (see table). Prior to the operation in May, 1950, the average of 30 leukocyte counts done in both phases over a two month period was 3,960 per cubic millimeter. In the early postoperative period of June to November, 1950, a similar average was 5,980. Two years later, in August and September, 1952, the average was 6,220. Similar effects have been noted by Monto, Doan, and Löffler. The increase in average number of leukocytes, without improvement in the degree of periodic neutropenia, was evidently not sufficient to raise the resistance to infections to a point at which they were eliminated. The complete relief of symptoms during two pregnancies is noteworthy, although no explanation is available. It is unfortunate that consecutive blood cell counts were not obtained during these periods.

Total Leukocyte Counts in Patient with Cyclic Neutropenia

Accurate diagnosis of this entity is important, for the disorder must be differentiated from acute and chronic neutropenia. Only by doing serial differential blood cell counts can this be accomplished. Other important diagnostic features are (1) a history of recurrent infections of the skin or mucous membranes over a period of years, possibly from infancy, (2) the presence of recurring cycles of neutropenia or agranulocytosis coinciding with these episodes, and (3) the sustained good general health of the person. Once the diagnosis is made, wise management of the patient can greatly ameliorate the economic consequences of a life-long periodic illness.

SUMMARY AND CONCLUSIONS

Cyclic neutropenia in a 16-year-old girl observed over a four year period is described. Splenectomy was not followed by relief from periodic infections. No effect on the regularity of the cycles or on the degree of neutropenia resulted; however, the total leukocyte count increased from an average of 3,960 before splenectomy to an average of 6,220 per cubic millimeter two and a half years later. Spontaneous relief from infections occurred during two pregnancies.

A review of eight cases collected from the literature shows that splenectomy will most likely be beneficial in the elderly patient with considerable splenomegaly. Little or no benefit may be expected if the patient is under 25 years of age and if the spleen is normal or slightly enlarged.

VACCINIA OF THE EYELIDS

TREATMENT BY AUREOMYCIN IN A SECOND CASE

Col. John H. King Jr.
and
Major Robert L. Forrest, (MC), U. S. Army
Washington, D. C.

Vaccinia of the eyelids, although not a rare condition, is uncommon and may cause serious ocular complications. Contact infection from others with vaccinia is probably commoner than autoinoculation.[1] In about one-third of the cases, the cornea becomes involved,[2] and vaccinial diskiform keratitis and necrosis may result in loss of the eye. Untreated vaccinia usually runs a course of 28 to 31 days. Crusting may appear after the 12th day, followed by a varying period of ulceration. When large areas of the lid margins are involved, thickening may persist for several months and gradually disappear or may be followed by permanent distortion or symblepharon.[3] The infection may spread to the other eye, and necrosis may follow secondary infection.[1]

Treatment in the past has been concerned chiefly with the symptoms, maintenance of sanitary conditions, and application of various antiseptic solutions locally. Atkinson and Scullard [2] advised therapeutic measures aimed specifically against the vaccinia virus. These appeared valuable in experiments with animals but had not been applied to human beings. Potassium permanganate applied locally and ascorbic acid given orally were recommended because it was thought that their oxidizing properties might inactivate the virus.

One of us (J. H. K.)[4] treated a 2-year-old patient who had severe, primary vaccinia of the eye with aureomycin supplemented by several of the measures mentioned above. The cure was dramatic and rapid; the lesions improved in 24 hours and disappeared completely in 4 days. It was felt that aureomycin exerted a definite rapid antiviral action in this case. Atkinson,[5] using the same antibiotic, obtained a good response in a patient with vaccinia of the eyelids complicated by early corneal involvement. Sichi [6] also used aureomycin, by mouth only, for the rapid cure of a case of severe vaccinia of the conjunctiva.

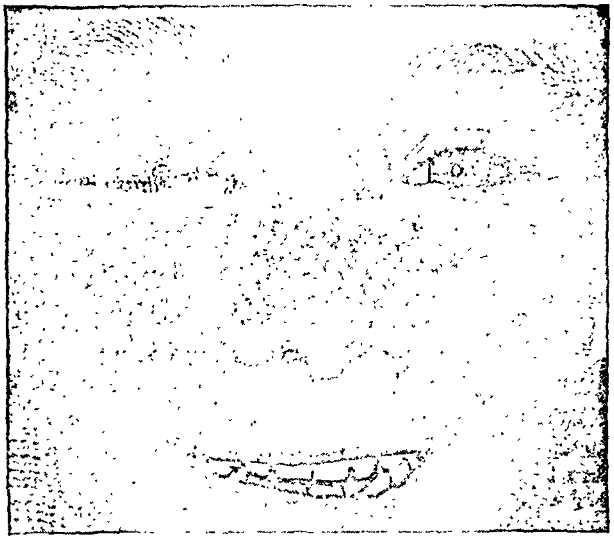

Fig. 1.—Vaccinia of the eye with facial edema.

REPORT OF A CASE

Ten days before admission to the hospital, a 6-year-old white girl was vaccinated on the left upper arm. A lesion typical of vaccinia developed. Six days after the vaccination, the child's mother noticed a slight redness and swelling of the right eyelids. During the next four days, ulcerated areas developed on the medial aspect of the right upper lid, with marked edema and redness. The lids swelled shut, and ulcers developed on the skin of the lower lid coming in contact with the lesions of the upper lid. Two days after the onset, the patient was taken to a physician and was given a dose of 600,000 units of penicillin intramuscularly. Streptomycin ointment was applied locally four times daily. Two days of this treatment failed to alter the progress of the lesions.

When the patient was admitted to the hospital, the right eyelids and adjacent skin were so swollen that the globe could be observed only by forcing open the lids (fig. 1). There were four ulcerated lesions of the lids; the two on the upper lid were held in contact with the two on the lower lid by the edema (fig. 2). The surfaces of the ulcers were covered with yellowish-white membranes. The cornea and conjunctiva were normal. There was also a vaccinia lesion on the left upper arm. Except for a temperature of 101.2 F, there were no other physical signs. A portion of membrane from one eyelid lesion and one from the lesion on the left upper arm were

6. Sichi, W.: Personal communication to the authors, 1952.

sent to the virus laboratory to be cultured separately. A blood specimen was also taken to determine the patient's immunity to vaccinia.

The following therapy was instituted: aureomycin, 250 mg. every eight hours, was given by mouth for a total of 120 hours. Aureomycin (5.0 mg. per cubic centimeter) borate solution was used to flush the right eye and eyelids every four hours while the patient was awake, for five days. Potassium permanganate (1:100,000 solution made fresh daily) was applied by wet compresses four times daily for five days. Ascorbic acid, 50 mg. twice daily by mouth, was administered for five days.

Twenty-four hours after the treatment was instituted, the edema of the lids had receded, and the child was able to open the right eye. Temperature had returned to normal. In 48 hours the swelling had almost completely disappeared; the ulcerated areas of the lids had begun to heal; and eschars had formed. After 72 hours, all the ulcerations except one had healed, and the edema and inflammation had disappeared. At 96 hours the ulcers had healed completely, and only small indurated areas marked the location of the lesions. The patient was released from the hospital in five days, and aureomycin borate solution was used in the right eye for an additional four days.

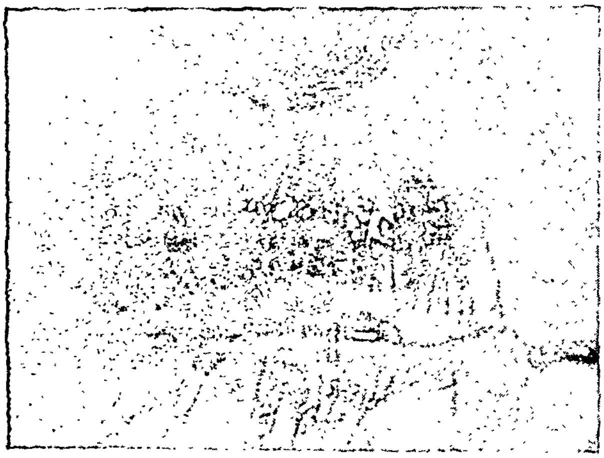

Fig. 2.—Ulcerated lesions in vaccinia of the eye.

The virus cultures taken from the lesions on arm and eyelids at the time of admission showed the same strain of virus. The blood specimen taken at the time of admission, as well as that taken two weeks later, revealed a rising titer of antibodies to vaccinia virus. The child was examined two weeks after discharge from the hospital, and no evidence of scarring of the lids was present.

SUMMARY AND CONCLUSIONS

Vaccinia of the eyelids, although uncommon, is a serious condition with complications that may cause the loss of vision. Severe vaccina of the eyelids in a 6-year-old girl that responded rapidly to aureomycin locally and orally is described. The etiology was proved by cultures and animal inoculation. In a previously reported case,[4] dramatic response was obtained by the same treatment, but with the addition of penicillin. In the present case, penicillin had been previously administered without results. In our knowledge, two other patients with vaccinia involving the eyes, one with corneal complications, also responded well to treatment with aureomycin. The early use of aureomycin, administered orally and locally, is recommended for the treatment of ocular vaccinia.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following article.

Ralph E. De Forest, M.D., *Secretary.*

CALCULATORS FOR APPLYING THE OGINO-KNAUS THEORY

The following statement is deemed necessary in order to counteract the misleading impact of some, though by no means all, of the advertising of devices sold to the public in connection with the so-called rhythm method of birth control. A considerable number of such devices for applying the Ogino-Knaus theory have been sold. The Council on Physical Medicine and Rehabilitation is charged with the responsibility of examining contraceptive devices that come into direct contact with the human body, and in its consideration of such devices has had the very helpful cooperation of an Advisory Committee on Sterility and Fertility. The various types of calculators, slide rules, and tables sold to the public for use in applying the rhythm method are not strictly within the purview of the Council because they are not directly applied to the human body. Nevertheless the Council has become concerned because the advertising literature that has been used to promote the sale of some of these devices in some instances has been quite misleading, while in other instances manufacturers have earnestly requested an opinion as to what could properly be claimed for such devices.

Eleven such devices, which have been studied in preparation of this report, will be described briefly for purposes of illustration.

1. A set of ovulation timetables is distributed mainly to physicians by a manufacturer of pharmaceuticals. The tables are printed on cards, with a system of pointers and several explanatory folders and sheets, and are intended to apply to patients whose cycles are 21, 24, 26, 28, or 30 days.

2. Another device consists of two aluminum disks between which a printed celluloid disk rotates. The device is enclosed in a purse-like leather case along with some printed matter addressed to the physician and claiming the approval of a distinguished clinician.

3. A cardboard box is equipped with a calendar in the form of a slender paper strip that slides through an arrangement of slots and tabs. A certain amount of information is printed on the box. No unreasonable claims are made, and the patient is advised, "In case of doubt, consult your physician or do not use the method at all."

4. A 16 page booklet has a pocket containing an arrangement of celluloid disks with a pointer. The textual material in the booklet is conservatively worded.

5. A similar 72 page leather-covered book has a pocket containing a similar calculating device. This consists of five laminas of celluloid bearing printed information and fastened together. The information in the book is carefully written and largely factual; it includes many quotations from ecclesiastical authorities and gives references to scientific publications.

6. Three cardboard disks so fastened together that they can be rotated are accompanied by a wealth of printed matter that seems to be carefully written.

7. A plastic device offered by a foreign manufacturer contains a roller that can be rotated. By appropriate settings of various graduated scales, one can read the days assumed to be fertile or sterile.

8. A circular cardboard disk, advertised as being "scientific," is embellished with a seductive figure of a woman and marked with card-players' symbols for heart, diamond, spade, and club. The disk rotates on a cardboard square on which a

circle is laid off into 365 divisions to represent the days of the year.

9. A device resembling a slide rule is described by the promoter as a "new automatic device that forecasts the days of the month when pregnancy is possible and impossible . . . based upon the discovery . . . that women can become pregnant only two days a month and that these days can be determined accurately in advance . . . the most fool-proof method of spacing birth known to medical science. Dr. ——, M.D., writing in the *American Medical Association Journal* reports not a single pregnancy in almost 16,000 cases where the system was used. . . . More dependable than any mechanical contraceptive, the System is sanctioned by all churches, is legal, and is preferred for psychological and moral reasons."

10. Another device consists of a slotted cardboard box with a roll of paper inside. The paper strip has the days of the year printed on it and is drawn out through the slot in such a way as to pass under an adjustable piece of cardboard bearing the words "sterile" and "fertile." By adjusting this piece and pulling the paper strip out of the box the user can make the intended calculation.

11. Probably the neatest and easiest to use of the devices examined is a 212 page book resembling a collection of logarithm tables. A woman who has observed her own menstrual cycles long enough to be able to state a maximum and a minimum length of cycle (for example, 33 days maximum and 24 days minimum during a given period of observation) finds two pages of explicit tables listing the "baby days" following any one of the possible 365 days on which the previous menstruation began. While the tables must be commended as a clear and accurate presentation of the results of calculations based on certain assumptions, the accompanying text does not accurately reflect the current opinion of either medical or ecclesiastical authorities. The following passages are examples: "Full recognition of the . . . Rhythm Method is evidenced by the medically authoritative *Journal of the American Medical Association* which stated 'Enough evidence has already been established to indicate that a strict observance of the method . . . is insurance of sterility even beyond that associated with the employment of most of the contraceptive apparatus and medicaments.' . . . All churches have accepted the Rhythm Method because it follows natural, biological control. . . . Artificial contraception does violate religious, legal and ethical principles."

In connection with the aforementioned items it seems desirable that the following statements be made, however self-evident they may seem to the regular readers of The Journal:

1. There is no scientific objection to tables, slide rules, or nomograms giving the results of calculations of "baby days" and "sterile days" if the assumptions underlying the calculations are explicitly and clearly stated, if the element of probability (as contrasted with certainty) is duly emphasized, and if the accompanying text is free from misleading or exaggerated statements.

2. It is important that the rules of semantics be obeyed in explanatory or apologetic material accompanying such devices and, in particular, that the words always, usually, sometimes, rarely, never, all, most, many, some, few, and none be used with care. The ethical or religious opinions of any one authority should not be given as representing all systems of philosophy or all religious groups, and the statement of any single investigator or editor should not be treated as if it were the unanimous verdict of a large professional group.

3. Semantically treacherous expressions like "natural," "artificial," and "nature's method" should be avoided, especially when irrelevant.

4. The following limitations of the rhythm method should be admitted: (*a*) It presupposes long periods of abstinence in addition to the briefer periods related to each menstrual cycle. (*b*) It makes no provisions for men, such as soldiers, whose occupation keeps them away from home except for brief and irregular periods of leave. (*c*) It "can be depended upon only by the normal, healthy woman and only under normal accustomed conditions." An appreciable number of patients without physically evident abnormality experience cycles shorter than 20 days or longer than 40 days, and the method is more and more unsuitable the greater the deviation from the assumed regularity. (*d*) It involves backward calculation from an anticipated event; the hazards of this process should be appreciated by whoever chooses it.

5. Despite the conviction, explicitly stated and tenaciously held by some authorities, that ovulation in women occurs on the 15th day before menstruation, other investigators continue to report evidence that the figure varies. Occasional intervals as short as nine or eight days have been indicated by a study of temperature charts. This uncertainty leads to the conclusion either that the number of "safe" days must be further curtailed or that the rhythm method must be supplemented by additional contraceptive precautions when pregnancy is strongly contraindicated.

6. It should be noted in connection with all these devices that they cannot do any more than an intelligent person can accomplish with paper and pencil, a calendar, and the necessary facts of observation and that they have a positive usefulness in increasing the probability of desired pregnancy in addition to the negative usefulness in contraception.

The foregoing statements are made necessary by repeated, sometimes misleading, references to the American Medical Association in the advertising of calculators for applying the Ogino-Knaus theory and are intended to apply only to the scientific aspects of the subject.

APPARATUS ACCEPTED

The following additional product has been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

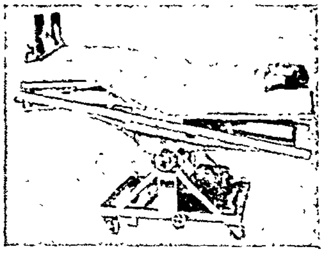
Ralph E. De Forest, M.D., *Secretary*.

Emerson Rocking Bed, Standard Hospital Model.

J. H. Emerson Company, 22 Cottage Park Ave., Cambridge 40, Mass.

The Emerson Rocking Bed is an apparatus designed to aid the respiration of patients with poliomyelitis during the transition from dependence on the tank type of respirator to independence. The rocking bed may provide necessary breathing aid for patients with partial but not extreme paralysis of the breathing muscles. The rocking bed is not intended to be substituted for the tank type respirator.

The apparatus measures 120 (high) by 200 by 92 cm. (4 by 6½ by 3 ft.) and weighs 227 kg. (500 lb.). Crated for shipment it measures 244 by 137 by 122 cm. (8 by 4½ by 4 ft.) and weighs 250 kg. (550 lb.). It operates on a standard light circuit and draws 782 watts. The motor requires 115 volt alternating current at 60 cycles, unless otherwise specified.



Emerson Rocking Bed, Standard Hospital Model.

When the bed is in operation, it oscillates about a fulcrum that is 16 to 18 cm. (7 to 8 in.) below the level of the patient's body, producing a to-and-fro motion. At the same time the longitudinal axis of the patient's body tilts +30 to −30 degrees about the horizontal and makes a total oscillation of 60 degrees. The speed is adjustable to conform with the patient's normal breathing rate, that is, from 15 to 26 oscillations per minute.

ARMED FORCES FACED WITH SURPLUS OF MEDICAL OFFICERS

A series of events have taken place within the past two months that has drastically changed the military medical manpower picture. These changes and the current situation are herein outlined in detail so that physicians may know what their probable military status will be during the next few months.

As recently as July 1 of this year it was the stated opinion of officials of the Department of Defense that the requirements of the Army for medical officers could not be met without recourse to a medical draft call by the Selective Service System. A request for 524 physicians was officially made by the Secretary of Defense to the Director of the Selective Service System, who acted immediately to effect the call-up of these physicians through state and local Selective Service agencies. Shortly thereafter a flood of applications for reserve commissions and active duty orders was received from physicians primarily in priorities 1 and 2 who had previously been temporarily deferred for reasons of essentiality and to complete internship and residency training. These volunteers now exceed 1,200, a number far in excess of the present medical requirements of all of the branches of the armed forces combined.

The termination of hostilities in Korea, a decision on the part of certain medical officers to extend their current tour of military duty until 24 months of service is completed, and the reduction in the ratio of physicians to troop strength ordered by the Secretary of Defense all served to increase the surplus. Notwithstanding this excess of medical officers, the Selective Service System refused to cancel its pending draft call, which forced 524 additional doctors to accept reserve commissions and apply for immediate active duty or be drafted as privates by August 28.

The Army has announced that no more applications for commissions will be accepted after September 1 and is frantically urging its excess reservists to delay their requests for active duty for as much as one year. Even those who are insisting that they be called immediately cannot be placed in training classes until November or December at the earliest. It appears to be certain not only that the current draft call was unnecessary but that there will be no more such calls for many, many months to come.

It is apparent that as a result of this situation many hysicians and local communities will be seriously inconvenienced. Acting in good faith and on the basis of the assertions by officials in Washington that medical personnel was sorely needed, many of these men have closed their offices or have discontinued their plans for additional residency or postgraduate training. In many instances this discontinuance of training was forced on them because of the prohibition that prevented hospitals from accepting priority 1 and 2 men to fill available residency vacancies.

Having terminated their civilian commitments on the assumption that they were needed immediately by the armed forces, these physicians are now faced with the prospect of an indefinite status for the next year or more. Possibly it is still not too late for many of them to change their plans, to request a delay in call to active duty, and resume their civilian occupations.

The alternative to a delay in the issuance of active duty orders to these men is the immediate call-up of an excessive number of medical officers. The disastrous long-range effects of this action would be: a wastage of medical manpower that would result in a reduction in the number of physicians available to care for the civilian population; a tendency to use excess medical officers on nonmilitary assignments; a squandering of available medical registrants under the "Doctor-Draft" law, which would accelerate the call-up of doctors in priorities 3 and 4; an inefficient utilization of physicians in uniform, with a resulting lowering of morale and general dissatisfaction with military service; and a nullification of the newly established ratio of 3 per 1,000 between medical and over-all troop strength, a goal that has been extremely difficult to attain.

The government officials charged with the administration of the "Doctor-Draft" law are obligated to call to active duty only those physicians who are needed and immediately to advise medical reservists as well as Selective Service medical registrants when they can expect to be called for military service.

FARM ACCIDENTS

One of the most hazardous of all occupations today is farming. In 1952, 62 out of every 100,000 farm residents lost their lives as a result of some sort of farm accident. An additional 1,200,000 farm residents suffered injuries. Most such accidents were preventable, and usually only one person was to blame—the person involved in the accident.

Farming has the third highest death rate among the major industries in the nation, surpassed only by the mining and other extractive and construction industries, it was reported in the current "Accident Facts" published yearly by the National Safety Council. Motor vehicle accidents among farm residents accounted for 6,000 deaths and 210,000 injuries, home accidents for 3,500 deaths and 540,000 injuries, occupational accidents for 3,800 deaths and 320,000 injuries and public non-motor-vehicle accidents such as streetcar or sidewalk mishaps for 1,300 deaths and 150,000 injuries.

Increasing use of machinery on farms may be a causative factor in the high death rate. There were about 700 fatal and about 25,000 nonfatal accidents involving farm wheel tractors in 1952. Fifty-five per cent of these deaths resulted from overturned tractors, and 16% were the result of falls from the vehicle. In 8% the victim was run over by the tractor, and in 5% he was crushed between the tractor and another object. Three per cent of such deaths resulted from entanglement, and 13% from other and unspecified causes.

Farming is one of the few occupations in which children are permitted to be close to operating machinery. It is no wonder, then, that one-third of the 306 fatal tractor accidents reported by Wisconsin and Ohio to the National Safety Council over a period of several years involved persons under 20 years of age. One case in 10 involved a child under 5 years of age. Deaths among the very young often resulted from falls that occurred while the children were riding on tractors.

One-third of the tractor fatalities in Minnesota and Iowa during 1949-1951, as reported to the National Safety Council, occurred in highway accidents. Considering the small proportion of time that tractors are on the highways, the accident rate during this use is probably much higher than the rate during use on the farm.

On the basis of corn harvest accidents in Iowa during 1952, it has been estimated that doctor and hospital costs per accident average $160, while the time lost averaged 30 days.

Farmers must be as accident conscious as their city friends. Since carelessness is responsible for most farm mishaps, they must realize that caution is synonymous with common sense. Such advice from a physician offers just as much preventive medicine as a vaccination against smallpox or the purification of drinking water.

Most physicians are close to their patients and take a personal interest in their welfare. This relationship is even more pronounced in the rural areas, where the physician and the farm resident usually share more than a patient-physician affinity. Therefore, the rural physician is in an ideal position to proffer advice that may prevent farm accidents. Every rural physician should volunteer safety facts and fallacies. It may be too late when the information is sought.

DENTAL FOREIGN BODIES IN THE LUNG AND ESOPHAGUS

Dental foreign bodies that have found their way into either the lung or the esophagus constitute a relatively small but important part of endoscopic practice. According to Hagens,[1] there are three main sources from which these cases originate. In the first group, a tooth or portion of a tooth, an inlay or filling, tartar, a piece of plaster impression, or a broken part of an instrument may slip from the grasp of the dentist and be aspirated or swallowed before the material is recovered. A second source of dental foreign bodies is supplied by patients who permit their teeth and dentures to fall into a deplorable state of disrepair. During the act of eating or swallowing, for example, a portion of the denture is broken, swallowed, and lodged in the esophagus, an event requiring endoscopic intervention. In the last group, teeth are loosened and sometimes lost as the result of manipulation of mouth gags and instruments during surgery in which a general anesthetic is used; this occurs especially in children undergoing tonsillectomy and adenoidectomy.

In general, patients should be carefully examined just as soon as it has been established that a dental foreign body has been swallowed. Roentgenograms are most helpful, not only in demonstrating the presence and site of the foreign body itself but also in displaying the reaction of tissues surrounding the object. When barium is used in the esophagus, it may stop at the level of the foreign body and, in some instances, cling to part of it. A tooth lodged in the bronchus of a child frequently produces high fever and a persistent cough, as well as other signs and symptoms pointing to the presence of a foreign body in the lung. Hagens asserts that in the case of two patients gold inlays slipped from the dentist's grasp; in one patient, a tooth was aspirated during the process of extraction; in another patient, a piece of dental plaster was aspirated; in two patients, dentures loosened during the act of swallowing; and, finally, in two patients, there was loss of a tooth during surgery of the throat.

WILLIAM VOLKER FUND

The establishment of the William Volker Fund extends the grants-in-aid program of the Committee on Research of the Council on Pharmacy and Chemistry into the basic medical sciences. When first organized as the Therapeutic Trials Committee, and up to the present, its fundamental objectives were to stimulate progress in the control and treatment of disease through facilitating investigations to establish the usefulness of diagnostic, preventive, and therapeutic agents.

The Board of Trustees of the American Medical Association in accepting a block grant from the William Volker Charities for administration by the Committee on Research also created an important precedent. Their decision establishes a pattern that may be followed by other large philanthropic organizations that desire to make contributions to the health field. By this mechanism grantors are guaranteed an impartial board of medical review by outstanding scientists well prepared to evaluate the proposed experiments. The entire grant will be spent on medical research, since the costs of customary overhead are borne by the American Medical Association.

The William Volker Fund is not specifically restricted to grants in special fields such as heart disease, cancer, or hypertension. The Committee on Research feels that this is commendable, since the progress of medical research requires broad investigations in all fields of medical endeavor, including the basic sciences. This approach should furnish better understanding of the normal cell and organ functions than can be secured by research directed primarily to departures from the normal processes.

Grants from the fund will be made to individual applicants and will be limited to the range of $500 to $1,000. The funds may be applied to defray expenses attendant to research, with the exception of salaries, services, and travel. Applications may be secured by addressing Dr. E. M. K. Geiling, Chairman, Subcommittee on Grants-in-Aid, Committee on Research, Council on Pharmacy and Chemistry, American Medical Association.

MEDICAL NEWS

ALABAMA

Narcotic Violation.—Dr. William J. Craig, Florence, Ala., pleaded *nolo contendere* in the United States District Court at Huntsville to a charge of violating the federal narcotic law, and on April 7 was placed on probation for three years.——On June 4, Dr. Horace Greeley Franklin, Thorsby, pleaded guilty in the U. S. District court of Montgomery to violation of the federal narcotic law and was sentenced to a term of 15 months.

Dr. Whetstone Day in Sylacauga.—By official proclamation, Aug. 2 was declared "Dr. Whetstone Day" in Sylacauga in honor of Dr. Adair K. Whetstone. The proclamation stated, in part, that Dr. Whetstone had "performed outstanding medical service and (had) constantly rendered his professional services without thought of personal reward and . . . (had) been an outstanding citizen and (had) reared and educated eight daughters and two sons who also are honorable citizens and who have made fine contributions to this community. . . ." Churches throughout the city paid tribute to Dr. Whetstone at their morning services, and at First Methodist Church, where Dr. Whetstone has served as steward for 51 years, three scholarships in his name were awarded to the Sylacauga Hospital School of Nursing. Dr. James S. McLester, Birmingham, presented the scholarships. Dr. James O. Morgan, Gadsden, president of the Medical Association of the State of Alabama, was speaker at the afternoon program at Noble Park.

CALIFORNIA

Dr. Cutting Named Acting Dean.—Dr. Windsor C. Cutting, professor of therapeutics, Stanford University School of Medicine, Stanford University-San Francisco, has been named acting dean of the school to succeed Dr. Loren R. Chandler, who has resigned after a 20 year tenure but will continue as professor of surgery. Dr. Cutting, who has been affiliated with the faculty since 1938, will continue to serve as head of the department of pharmacology and therapeutics. Dr. Cutting, a member of the A. M. A. Council on Pharmacy and Chemistry and of the executive committee of the U. S. Pharmacopeia, is editor of "Annual Review of Medicine" and is on the editorial board of "Excerpta Medica."

COLORADO

County Society Library.—Ground has been broken at Franklin St. and East 19th Ave., Denver, for the new $300,000 Denver County Medical Society library. The land, located at the southwest corner of the Presbyterian Hospital grounds, was given the society by the Presbyterian Hospital Association. The library building will also house the offices of the county medical society. Among those participating in the ceremonies were Drs. Nolie Mumey, president of the Presbyterian Hospital Association, Lumir R. Safarik, president of the county medical society, William A. Liggett, president of the Colorado State Medical Society, W. Bernard Yegge, chairman of the county society's board of trustees, Walter W. King, medical society librarian, and James M. Perkins, all of Denver.

Personal.—Dr. Walter H. Prockter, Nucla, has been named company physician for the United States Vanadium Corporation in Uravan.——Dr. Frank H. Zimmerman, superintendent of the Colorado State Hospital at Pueblo, was recently awarded a citation by Gov. Dan Thornton on completion of a quarter century of service at the institution.——Col. Carl W. Tempel, chief of medical service, Fitzsimons Army Hospital, Denver, recently delivered the annual Hyman I. Spector lecture at the St. Louis University School of Medicine.——Dr. John D. Gillaspie, mayor of Boulder, has been named a director of the First National Bank to fill the vacancy caused by the resignation of Robert L. Stearns, former president of the University of Colorado.——Dr. Freburn L. James, formerly of Glendale, Calif., has been appointed pathologist of the Boulder-Colorado Sanitarium and Hospital and the County of Boulder General Hospital in Boulder. Dr. James was recently affiliated with the Army Hospital in Camp Roberts, Calif.

IDAHO

State Medical Election.—At the annual meeting in Sun Valley the Idaho State Medical Association elected Dr. E. Victor Simison, Pocatello, president and Dr. Alexander Barclay Jr., Coeur d'Alene, president-elect and reelected Dr. Robert S. McKean, Boise, secretary-treasurer.

ILLINOIS

Health Council Appointed.—Dr. Robert H. Bell was recently appointed chairman of an advisory council to the Carlinville department of health, of which Dr. William W. Lusk, health officer, is an ex officio member. Dr. Robert H. Rutherford has been named special adviser, health agencies. The appointments are the result of a petition endorsed by local physicians, the Carlinville area hospital administrator, and the hospital auxiliary president, suggesting formation of a professional health department that would make recommendations pertaining to health and sanitation to the board of health.

Chicago

Personal.—Dr. Benjamin M. Gasul will deliver a series of three lectures at the City of Hope, Duarte, Calif., and the Cedars of Lebanon Hospital, Los Angeles, on "Recent Advances in Pediatric Cardiology" during the first week of September.

Meetings of Naval Reserve Medical Unit.—Medical Unit 9-20, U. S. Naval Reserve announces the following programs to be held at the U. S. Naval Reserve Armory, Randolph St. and the lake, 8 p. m.

Sept. 8, Brain Injury (movie).
Sept. 15, Arthur R. Colwell, Selective Treatment of Diabetes Mellitus.
Sept. 22, Robert H. Ebert, Newer Therapy of Tuberculosis.
Sept. 29, John Van Prohaska, Multiple Organ Resections for Carcinoma.

IOWA

Dr. Bierring Retires as Health Commissioner.—The Iowa State Medical Society recently adopted a resolution commending Dr. Walter L. Bierring, Des Moines, for his contributions to medicine in Iowa and recommended that he be placed on the list of "all-time great physicians of our state." Dr. Bierring, 84, recently retired as state health commissioner. At a testimonial dinner at the Des Moines Club, given by the state board of health, a certificate of appreciation was presented that read, in part: "We present this token of the gratitude of the people of Iowa for the 60 years you have so faithfully devoted to the improvement and preservation of their health. The accomplishments of your most distinguished career are only surpassed by the graciousness and efficiency with which you have conducted the office of commissioner during the past 20 years." Dr. Bierring, who was President of the American Medical Association in 1934, has served also as president of the Iowa State Medical Society, the Johnson County Medical Society, and the Polk County Medical Society. In 1954, he will have been president of Alpha Omega Alpha for 20 years.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

KANSAS

Pediatric Society to Be Formed.—Plans for the organization of a Kansas pediatric society will be discussed at a meeting for Kansas pediatricians and all physicians interested in pediatrics at Emporia, Sept. 19. Arrangements are being completed by a committee composed of Drs. Charles T. Hinshaw, Wichita; William H. Crouch, Topeka, and David R. Davis, Emporia. There will be an all-day scientific program, presented by out-of-state pediatricians, with a two-hour luncheon period devoted to round-table discussions. Physicians interested should write immediately to Dr. David R. Davis, 103 Gazette Bldg., Emporia.

KENTUCKY

Home Accident Prevention Program.—The W. K. Kellogg Foundation of Battle Creek, Mich., has granted $107,540 to the Kentucky State Department of Health for a three year home accident prevention program. Full support will be given by the foundation for the first two years. The state will assume some financial cost in the third year and, it is anticipated, will support the project entirely thereafter.

Personal.—Dr. Keith P. Smith, chief of staff, Corbin Municipal Hospital, was recently elected president of the Kentucky Academy of General Practice and vice-president of the Kentucky State Medical Association. Dr. Smith, who was formerly associated with his father, the late Dr. Festus S. Smith, and a brother, Dr. Truman S. Smith, previously served as manager of the Smith Hospital.——Dr. T. Eugene Andes, formerly clinical director of State Hospital, Morganton, N. C., has been named clinical director of Central State Hospital at Lakeland, to succeed Dr. Charles D. Yohe, who has become clinical director of Kentucky State Hospital, Danville.——Dr. Robert F. Hansen, former coordinator of preventive medical services for the state department of health, has been appointed deputy director of the city-county health department in Louisville. He will also be associate professor of community health at the University of Louisville Medical School.——Dr. J. Duffy Hancock, Louisville, president-elect of the Kentucky State Medical Association, has been named president-elect of the 12 state Southeastern Surgical Congress.——Dr. Jack L. Chumley, Louisville, has been appointed associate editor in charge of scientific content of the *Journal of the Kentucky State Medical Association*.——Dr. Donald L. Martin, Louisville, a surgeon at Veterans Administration Hospital, recently accepted an assignment as medical missionary in the Belgian Congo from the American Baptist Foreign Mission Society.——Dr. Edward Wilson, Pineville, was recently honored at a dinner at the Pineville Community Hospital, which he helped to found. On completion of 50 years of practice, his associates presented him with a plaque, and employees of the hospital gave him binoculars. Dr. Wilson's eldest son, Dr. Edward S. Wilson, is associated with him in practice.

MARYLAND

Dr. Becker Named Professor of Ophthalmology.—Dr. Bernard Becker, Baltimore, has been appointed professor and head of the department of ophthalmology, Washington University School of Medicine, St. Louis, replacing Dr. Lawrence T. Post, who retired from these duties July 1. Until Dr. Becker assumes his duties, about Jan. 1, 1954, Dr. Theodore E. Sanders will be acting head of the department.

MICHIGAN

Society News.—The Detroit Academy of Orthopedic Surgery has elected the following officers: president, Dr. Francis P. Walsh, vice-president, Dr. Peter G. Shifrin, and secretary-treasurer, Dr. John Lyford. The regular meetings of the Detroit Academy of Orthopedic Surgery will be held at the University Club at 6:30 p. m. on the second Monday in October, November, and December, 1953, and January, March, April, May, and June, 1954.

Is There a Doctor in the House?—A new call system, which is of interest to members of the medical profession, has been placed in operation at the Krim Theatre in Detroit. This ingenious call system will allow a physician to keep in touch with his office, hospital, or home while at this theater. It operates as follows: On entering the theater, the physician may present his card to the theater cashier, who will give him a designated number. When a call for him is received, the cashier throws a switch on a control panel in the box-office. This lights up the physician's number on a special panel screen on the left side of the stage. On seeing his special number on this screen light up, the physician proceeds to the manager's office and accepts his call over the private telephone line reserved for this purpose.

MINNESOTA

Hobby Awards.—Winners of first place awards in the Physicians' Art and Hobby Show at the 100th annual meeting of the Minnesota State Medical Association include: Drs. John P. Wendland, Minneapolis, photography; Harold J. Rothschild, St. Paul, drawing; James L. Benepe, St. Paul, oils; James J. Berens, Rochester, handicraft; Robert L. Wilder, Minneapolis, sculpture; and Alexander E. Ratelle, St. Paul, popular vote of convention visitors for his "Portrait of a Lady."

MONTANA

State Society's Jubilee Meeting in Billings.—The 75th anniversary meeting of the Montana Medical Association will be held at the Eastern Montana College of Education, Billings, Sept. 17-20, under the presidency of Dr. James M. Flinn, Helena. Guest speakers and their first presentations include:

James B. Brown, St. Louis, Management of Compound Facial Injuries.
William G. Klingberg, St. Louis, Erythroblastosis Fetalis.
John E. Hobbs, St. Louis, Office Treatment of Gynecological Problems.
Charles K. Petter, Waukegan, Ill., Evaluation of Newer Methods in Treatment of Tuberculosis.
J. William Thompson, St. Louis, Surgical Diseases of the Biliary Tract: Practical Points in Management.
Joseph C. Edwards, St. Louis, Diagnosis and Treatment of Essential Hypertension
Alson E. Braley, Iowa City, Emergency Care of Ocular and Periocular Injuries.

Clinical pathological conferences will be held Thursday and Friday at 1 p. m. The annual reception and banquet will take place at the Northern Hotel, Thursday, 6:30 p. m., with Dr. Everett H. Lindstrom, Helena, as toastmaster. Mr. Robert B. Richardson, Helena, president, Western Life Insurance Company, will deliver an address on "The Penalty of Prominence." Friday evening the Yellowstone Valley Medical Society, under the presidency of Dr. Edward W. Gibbs, will be host to all members and guests of the association at a reception, 7-9 p. m., at the Yellowstone Country Club, 1701 Rimrock Road, Billings.

NEW YORK

Course on Glaucoma.—A course on glaucoma with particular emphasis on gonioscopy and study of the anterior angle will be given at the Brooklyn Eye and Ear Hospital, Nov. 16-18, by Dr. Daniel Kravitz and staff. Application and the fee of $40 for registration by ophthalmologists may be addressed to Dr. Daniel Kravitz, Brooklyn Eye and Ear Hospital, 20 Greene Ave., Brooklyn 38.

Cancer Meeting at Rochester.—During postgraduate day at the Rochester General Hospital, Sept. 17, the morning sessions will be devoted to clinics on the various types of tumors and the afternoon to a symposium on the nonsurgical treatment of neoplastic diseases by a panel from Memorial Center for Cancer and Allied Diseases, New York. Dr. Joseph E. Rall will discuss "Use of Radioactive Isotopes in the Treatment of Cancer" and Dr. George C. Escher "Hormonal Therapy in Neoplastic Disease." This course is sponsored by the New York State Department of Health, the New York State Medical Society, the New York State Academy of General Practice, and the Rochester Regional Hospital Council.

New York City

Course in Radiological Safety.—A 15 week course in radiological safety, beginning Sept. 23, is offered by the department of industrial medicine, Post-Graduate Medical School of New York University-Bellevue Medical Center, in cooperation with the U. S. Atomic Energy Commission and New York University College of Engineering. The course will be held at the Institute of Industrial Medicine, 325 E. 38th St., Wednesdays, 4-6 p. m. It is designed to acquaint industrial hygienists, insurance engineers, health officials, safety engineers, industrial physicians, and users of radioisotopes and x-ray equipment with the fundamentals of radiation safety. A laboratory course, 7-10 p. m., to run concurrently for a limited number of those taking the lecture course, will permit practical work with survey and monitoring instruments in evaluating radiation hazards. Tuition for each course is $60. For information, address: Office of the Dean, New York University Post-Graduate Medical School, 477 1st Ave., New York 16.

Dr. Day Named Professor at State University.—Dr. Richard L. Day, associate professor of pediatrics at Columbia University College of Physicians and Surgeons, will become chairman of the department of pediatrics at the State University of New York College of Medicine at Brooklyn, Dec. 1. He will be the first full-time professor of pediatrics on the college staff. Dr. Charles A. Weymuller, who has been professor and chairman of the department on a part-time basis since 1936, will continue as full professor on a part-time basis. Dr. Day has been affiliated with the Hartford (Conn.) Hospital and Babies and Willard Parker hospitals in New York City. He was instructor in pediatrics, Cornell University Medical College, and instructor in diseases of children, assistant and associate professor of pediatrics at Columbia University College of Physicians and Surgeons. He also served for three years as research assistant in maternal and child health to the Children's Bureau in Washington, D. C., and for two years during the war as physiologist of the U. S. Army Climatic Research Laboratory in Lawrence, Mass.

PENNSYLVANIA

State Medical Meeting in Pittsburgh.—The annual meeting of the Medical Society of the State of Pennsylvania will be held at the Hotel William Penn, Pittsburgh, Sept. 22-25, under the presidency of Dr. Theodore R. Fetter, Philadelphia. Out-of-state speakers include:

Mr. Henry C. Black, Battle Creek, Mich., Business Management of Medical Practice.
Brian B. Blades, Washington, D. C., Diagnosis and Criteria of Operability of Bronchogenic Carcinoma.
William S. McCann, Rochester, N. Y., Fundamentals of Cardiorespiratory Physiology in Reference to Differential Diagnosis and Treatment of Dyspnea.
Claude S. Beck, Cleveland, Cardiac Arrest and Resuscitation.
Carl P. Huber, Indianapolis, Management of Abortion.
Roger B. Scott, Cleveland, Treatment of External Endometriosis.
Frank W. Konzelmann, Washington, D. C., Selection and Interpretation of Liver Function Tests.
Herbert Z. Lund, Greensboro, N. C., Malignant Dermatological Lesions.
John A. Campbell Colston, Baltimore, Frequency of Cancer of the Prostate.
Robert M. McAllister, Camden, N. J., Diagnosis and Management of Poliomyelitis.
Nathan B. Talbot, Boston, Use and Misuse of Cortisone in Infancy and Childhood.

At the annual state dinner in the Pittsburgh Room, Tuesday 7 p. m., Dr. James L. Whitehill, Rochester, will be installed as the 104th president, and the Benjamin Rush Awards, poster contest prizes, and certificates to Graduate Education Institute enrollees will be presented. The president's reception and dance will be held Wednesday at 9 p. m. Various alumni dinners have been scheduled for Thursday. The Pittsburgh women physicians have arranged a luncheon for Thursday at 12 noon in the Duquesne Club, 325 6th Ave. All women physicians attending the annual session are cordially invited. Tickets ($4.50) may be purchased from Dr. Dorothy K. Nash, 4136 Bigelow Blvd., Pittsburgh 13. The Woman's Auxiliary will meet at the Roosevelt Hotel, Sept. 21-25.

UTAH

State Medical Meeting and Rocky Mountain Conference.—The 58th annual meeting of the Utah State Medical Association and the 7th biennial Rocky Mountain Medical Conference will be held at the University of Utah, Salt Lake City, Sept. 10-12. The address of welcome will be delivered by Dr. Kenneth B. Castleton, Salt Lake City, president, Utah State Medical Association. Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, will address the annual banquet at the Hotel Utah, Friday, 7:30 p. m., on "The Future of Medicine." His talk will be followed by a motion picture, "The Florida Everglades," presented by Dr. Russell G. Frazier, Salt Lake City. A social hour at the Alta Club will precede the banquet. Guest speakers for the scientific sessions and their first presentations include:

Edwin H. Ellison, Columbus, Ohio, Management of Intestinal Obstruction.
Priscilla White, Boston, Diabetes in Pregnancy.
James T. Priestley, Rochester, Minn., Surgical Lesions of the Adrenal Glands.
Meyer A. Rabinowitz, Brooklyn, Precordial Pain—Its Causes and Differential Diagnosis.
M. Digby Leigh, Vancouver, B. C., Emergency Complications of Anesthesia and Their Management.
Alexander D. Langmuir, Atlanta, Ga., The Changing Panorama of Medical Care and Its Implications in Medical Education.

Round-table discussions will follow luncheon Thursday and Friday. Color television clinics will be presented Thursday and Friday afternoons and Saturday morning, and on Friday at 8:45 a. m. there will be a color television chest panel. A social hour, 6:30 p. m., will precede the stag dinner for members of the Rocky Mountain Medical Conference and University of Utah Medical Alumni, which will be held Thursday at the Aviation Club.

VERMONT

Personal.—Dr. John P. J. Cummins was initiated recently into Alpha Omega Alpha, national honorary medical society. He was elected as a physician who typifies attributes of the "ideal general practitioner." Dr. Cummins and two sons, who are also graduates of the University of Vermont College of Medicine, Burlington, practice in Ticonderoga, N. Y.——Dr. Delbert D. Griffith, Bristol, who graduated from the University of Vermont College of Medicine, Burlington, June 14, received one of the five national $1,000 scholarship awards given annually by the Mead Johnson Company to a graduating senior, to enable him to take a year of general practice residency following internship.

Meetings on Cardiology.—A cardiovascular symposium, sponsored by the Vermont Heart Association in cooperation with the New Hampshire Heart Association and the University of Vermont College of Medicine, Burlington, will be held at Oakledge Manor, Burlington, Sept. 8-10. Guest speakers from the United States include Dr. Irvine H. Page, Cleveland (Neural and Hormonal Control of the Blood Vessels) and Dr. Henry A. Schroeder, St. Louis (Control of Hypertension). Registration fee, $2; no fee for members of the New Hampshire and Vermont heart associations, students, residents, and interns of New Hampshire and Vermont hospitals. For information write to Dr. Wilhelm Raab, University of Vermont College of Medicine, Burlington (Tel. 3-3451, ext. 33; 4-4511, ext. 349; or 3-3886).

Two cardiology seminars, both arranged by the division of experimental medicine, University of Vermont College of Medicine, and sponsored by the Vermont Heart Association, will be held Sept. 10-12. The seminar on "Hormones and Nerves in Cardiac Pathology and Therapy," conducted by Dr. Wilhelm Raab, professor of experimental medicine, University of Vermont College of Medicine, Burlington, will have as guest speaker Dr. Irvine H. Page. The following program will be presented:

Thursday, Medical College, Hall A, 2-5 p.m., Hormonal and Neurohormonal Influences on the Vascular System and on Myocardial Metabolism.
Friday, Medical College, Hall A, 8-10 p.m., Neurohormonal Pathogenesis and Treatment of Angina Pectoris and of Cardiogenic Shock.
Saturday, Bishop DeGoesbriand Hospital, Auditorium, 1:30-3 p.m., Hormonal Factors in the Origin and Treatment of Congestive Heart Failure.

The seminar on electrocardiography, conducted by Dr. Eugene Lepeschkin, associate professor of experimental medicine, University of Vermont, will have as guest speakers Dr. Charles E. Kossmann, associate professor, New York University College of Medicine, and Dr. Harold D. Levine, assistant clinical professor, Harvard Medical School, Boston. "The Normal Electrocardiogram and Its Limits" will be discussed Thursday, 8-10:30 p. m., and Friday, 8:30 a. m. to 12 noon. Discussions on "The Electrocardiographic Diagnosis of Myocardial Infarction" will be held Saturday, 8:30 a. m. to 12 noon and 8:30-10:30 p. m. Part of the afternoon will be kept free for inspection of the local hospitals and for sight-seeing trips on Lake Champlain and in the Green Mountains. Registration fees: seminar on hormones, etc., $5; seminar on electrocardiography, $10. No registration fees will be required of faculty and students of the University of Vermont and of residents and interns of Vermont hospitals.

WASHINGTON

State Medical Meeting in Seattle.—The annual meeting of the Washington State Medical Association will be held at the Olympic Hotel, Seattle, Sept. 13-16. Dr. Charles E. Watts, Seattle, will deliver the presidential address Tuesday, 11 a. m., in the Olympic Bowl. Dr. Frank E. Wilson, Director, A. M. A. Washington, D. C., office, will give a "Purview of Federal Medical Legislation." Guest speakers for the scientific sessions include:

Chester M. Jones, Boston, Trigger Mechanisms and Digestive Tract Symptoms.
Paul W. Schafer, Kansas City, Kan., Clinical Problem of Lung Cancer.
Alfred E. Maumenee, San Francisco, Recent Concepts of the Etiology and Treatment of Glaucoma.
C. Frederick Ferciot, Lincoln, Neb., Congenital Foot Conditions in Children.

On Tuesday morning, the ear, nose, and throat section will present a panel discussion on "The Cleft Palate and Harelip Problem." Wednesday, 2 p. m., a symposium on endocrinology will be held, with Dr. Robert H. Williams, Seattle, as moderator. At 2:50 p. m., a panel discussion on "Clinical Endocrinology" will be presented by Drs. Carl G. Heller, Portland, Ore., and Lester J. Palmer, John Bakke, and Robert H. Williams, Seattle. On Sunday at 6 p. m., there will be a no-host family dinner, honoring 50 year practitioners. Monday the Salmon Fishing Derby will start at Ray's Boathouse, at 5:45 a. m. The golf tournament will begin at the Seattle Golf and Country Club at 7:30 a. m. Tuesday noon the general practitioners' luncheon will be held in the Georgian Room, and the Washington State Medical Association Civil Defense Committee will meet in the Olympic Bowl. The annual banquet and ball, preceded by refreshments in the Olympic Bowl, 6:30 p. m., will be held in the Georgian Room (dress is optional). The Washington State Medical Association will be host for a public relations luncheon Wednesday, at which Dr. George F. Lull, Secretary and General Manager, will discuss "You and Your A. M. A.," and Mr. Rollen Watterson, executive secretary, Alameda-Contra Costa (Calif.) Medical Association, will speak on "Fundamentals of Public Relations for a Medical Society." The reception for new presidents, 6:30 p. m., Junior Ballroom, will honor Dr. Alvia G. Young, Wenatchee, Washington State Medical Association president, and Mrs. A. George Hanson, Seattle, auxiliary president.

WEST VIRGINIA

Meeting on Tuberculosis.—The annual meeting of the West Virginia Tuberculosis and Health Association will be held at the Hotel Fairmont in Fairmont, Sept. 9-10, in cooperation with the West Virginia Conference of Tuberculosis Workers, the West Virginia Trudeau Society, and the medical section of the West Virginia Tuberculosis and Health Association. Wednesday afternoon the West Virginia Trudeau Society will present the following program:

Ambulant Treatment of Tuberculosis with Drugs, Julius L. Wilson, Philadelphia.
Management of Chronic Cough, Edward Lebovitz, Pittsburgh.
Present Day Surgical Concept of the Treatment of Pulmonary Tuberculosis, Haven M. Perkins, Charleston.
X-Ray Symposium on Chest Diseases, Rupert W. Powell, Fairmont.

Dr. George F. Evans, Clarksburg, program chairman, urges all physicians who wish to have films reviewed, to have them at the conference. The general session of the West Virginia Tuberculosis and Health Association Thursday morning will include papers on "Nutrition in Tuberculosis Control" and "The Value of a Chest X-Ray for All Admissions to a General Hospital." The scientific session will close with an address by Mr. W. C. Handlan, Fairmont, director of advertising and publicity, Monongahela Power Company, whose subject will be "Public Relations Per Se."

WISCONSIN

Hearing Problems in Industry.—Clinics on hearing conservation in industry will be held in Wausau, Sept. 10, Oshkosh, Sept. 24, and Racine, Oct. 14, under the auspices of the Wisconsin Council of Safety, State Medical Society of Wisconsin, Wisconsin State Board of Health, Wisconsin Manufacturers Association, and the Wisconsin State Nurses Association. "Hearing Problems in Relation to Industrial Noise Exposure" will be discussed at Wausau by Dr. Aram Glorig Jr., Washington, D. C., and at Oshkosh and Racine by D. E. Wheeler, Ph.D., Los Angeles. Participants in a panel on "Responsibilities of Physicians and Nurses in an Industrial Hearing Conservative Program" will be Drs. Thomas L. Tolan, Meyer S. Fox, and Paul T. Whitaker, and Miss Ruth Martineau, R.N., all of Milwaukee. Registration may be arranged through the Wisconsin Council of Safety, State Office Building, Madison. The $5 fee includes luncheon.

GENERAL

Psychiatric Meeting in Kansas City.—The Mid-Continent Psychiatric Association, a district branch of the American Psychiatric Association, will meet at the Hotel President in Kansas City, Mo., Sept. 26-27. All interested members of the profession are invited. There is no registration fee. Among the speakers will be Drs. Kenneth E. Appel, Philadelphia, Daniel Blain, Washington, D. C., Lloyd J. Thompson, Winston-Salem, N. C., and Neville Murray, Galveston, Texas.

Fellowships for Basic Research in Arthritis.—The Arthritis and Rheumatism Foundation offers the following research fellowships in the basic sciences related to arthritis: (1) predoctoral fellowships, ranging from $1,500 to $3,000 per annum, depending on the family responsibilities of the fellow, tenable for one year with prospect of renewal; (2) postdoctoral fellowships, ranging from $3,000 to $6,000 per annum, depending on family responsibilities, tenable for one year with prospect of renewal; (3) senior fellowships for experienced investigation, carrying an award of $6,000 to $7,500 per annum and tenable for five years. Deadline for applications is Nov. 1. Applications will be reviewed and awards made by Feb. 15, 1954. For information address the Medical Director, Arthritis and Rheumatism Foundation, 23 W. 45th St., New York 36.

Roentgen Ray Society Meeting in Cincinnati.—The annual meeting of the American Roentgen Ray Society will be held at the Netherland Plaza Hotel, Cincinnati, Sept. 29 to Oct. 2. The meeting will be called to order at 8:30 a. m. by Dr. Charles L. Martin, Dallas, Texas, president. After an address of welcome by Dr. Stanley E. Dorst, dean, University of Cincinnati College of Medicine, the president-elect, Dr. Harry M. Weber, Rochester, Minn., will be installed in office and will deliver the inaugural address. Dr. David G. Pugh, Rochester, Minn., will serve as moderator for a symposium, "A Practical Consideration of Mitral Stenosis," Tuesday morning. Tuesday evening Dr. Paul C. Hodges, professor of radiology, University of Chicago School of Medicine, will deliver the Caldwell lecture on "Normal Bone, Diseased Bone, Dead Bone." Wednesday morning there will be a symposium on radiation protection, with Dr. Andrew H. Dowdy, Los Angeles, as moderator.

Surgeons Meeting in New York.—The annual congress of the United States and Canadian sections of the International College of Surgeons will be held at the Waldorf-Astoria in New York Sept. 13-17. Dr. William R. Lovelace, Albuquerque, N. Mex., is president of the United States section, and Dr. Douglas U. McGregor, *Hamilton, Ontario, president* of the Canadian section. The Monday morning session will be on "Advances in the Treatment of Cancer." Participants will include Drs. Charles S. Cameron, Cornelius P. Rhoads, and George N. Papanicolaou, New York. In other general assemblies, advances will be discussed in the treatment of cardiopulmonary diseases, thyroid surgery, surgery of stomach and intestines, surgical treatment of diseases of the esophagus, vascular surgery, and intervertebral disk lesions. A film forum will be held Monday evening, a forum on pharmacology in surgery Tuesday evening, the annual banquet Wednesday evening, and the annual convocation in Carnegie Hall on Thursday.

Obstetricians, Gynecologists, and Abdominal Surgeons.—The annual meeting of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons will be held at the Homestead, Hot Springs, Va., Sept. 10-12, under the presidency of Dr. Nicholson J. Eastman, Baltimore. Speakers by invitation include:

John C. Ullery, Philadelphia, Management of Pregnancy in Heart Disease.

William N. Thornton Jr., Charlottesville, Va., Late Urinary System Complications Following Radical Hysterectomy for Carcinoma of the Cervix.

Louis M. Hellman, Brooklyn, Factors Influencing the Occurrence of and Changes in the Reserve Cell in the Human Cervix.

W. Nicholson Jones, Birmingham, Ala., Role of Antibiotics in Management of Incomplete Abortions.

Ronald R. Greene, Chicago, Papillomatous Lesions of the Cervix.

Discussants by invitation will be Prof. John F. Cunningham, Dublin, Ireland, William K. Strother Jr., Dallas, Texas, William J. Dieckmann, Chicago, and Dr. Axel N. Arneson, St. Louis. The Joseph Price orator, Dr. Gordon King, professor of obstetrics and gynecology, Hong Kong University, will speak on "Advanced Extrauterine Pregnancy."

Tri-State Obstetric Seminar.—The maternal welfare committee of the Florida Medical Association and the bureaus of maternal and child health of South Carolina, Georgia, and Florida will sponsor an obstetric seminar at the Sheraton Beach Hotel, Daytona Beach, Fla., Sept. 14-16. Dr. Eugene F. McCall, Jacksonville, will serve as moderator for a discussion on "Maternal and Fetal Mortality Trends in South Carolina, Georgia, and Florida" by representatives from the state health departments and state medical associations. Dr. Hugh A. Carithers, Jacksonville, will speak on "Care of the Premature and Newborn Infant." Out-of-state speakers will present the following program:

Anesthesia and Analgesia in Obstetrics, John Adriani, New Orleans, or William H. Galvin Jr., Emory University, Ga.

Heart Disease in Pregnancy, Charles A. Poindexter, New York.

Caesarian Section, M. Edward Davis, Chicago.

Management of Prolonged Labor—Induction of Labor, Duncan E. Reid, Boston.

Abnormal Presentations and Forceps Delivery, Allan C. Barnes, Columbus, Ohio.

Bleeding in Pregnancy, Carl P. Huber, Indianapolis.

Care of the Premature and Newborn Infant, Robert B. Lawson, Winston-Salem, N. C.

Erythroblastosis—Resuscitation of the Newborn, Edith L. Potter, Chicago.

Mississippi Valley Medical Meeting.—The annual meeting of the Mississippi Valley Medical Society will be held at the Elks Club, Springfield, Ill., Sept. 23-25, under the presidency of Dr. John I. Marker, Davenport, Iowa. On Wednesday Dr. John A. Saxton, St. Louis, will serve as moderator for a clinical pathological conference. Thursday there will be a panel on diabetes, with Dr. Robert M. Kark, Chicago, as moderator. Dr. Alphonse McMahon, St. Louis, will be moderator for the noon round-table luncheon. The informal evening fellowship hour, banquet, and entertainment will be held Thursday. Dr. Melvin A. Casberg, Washington, D. C., assistant secretary of defense (health and medical), will speak on "The Health Professions and National Defense." Dr. Willis I. Lewis, *Herrin, Ill., president of the Illinois State Medical* Society, and Dr. E. Claude Bohrer, West Plains, Mo., president of the Missouri State Medical Association, will also address the evening meeting. Dr. Arthur H. Keeney, Louisville, winner of the first prize in the 1953 Mississippi Valley Medical Society essay contest, will read his paper on "Grass Roots in the Prevention of Blindness," and Dr. Robert L. Sanders, *Memphis, Tenn., honor award recipient, will present* "Gallbladder and Duct Problems, Medical and Surgical Aspects" (lantern slides). Dr. Walter R. Bett, London, England, will discuss "Medical History in Eponyms." Dr. William A. Bloom, Fayette, Mo., past president of the Missouri State Medical Association, will serve as moderator for the round-table luncheon on Friday and Dr. Daniel L. Sexton, St. Louis, as moderator of a panel, "What's New in Medicine and Surgery." There is no registration fee. For information, write to Dr. Harold Swanberg, secretary, 209-224 W.C.U. Bldg., Quincy, Ill.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

LATIN AMERICA

Pediatric Meetings.—The seventh International Congress of Pediatrics will be held Oct. 12-17 in Havana, Cuba, immediately after the annual meeting of the American Academy of Pediatrics in Miami, Fla., Oct. 6-9. The main topics will be "Epilepsy in Infancy and Childhood," "Diagnosis of Congenital Malformations of the Heart and Great Vessels Susceptible of Surgical Treatment," "Problems of the Premature Infant," "Complications of Primary Tuberculosis," and "Metabolism and Nutritional Problems." Round-table discussions will be held on the following topics: BCG vaccination, nephrosis in children, bacteriology in infantile diarrhea, antibiotics, virus diseases, neoplastic diseases, problems of hematology, pediatric surgery, and pediatric endocrinology. Among the physicians who will participate in the program are Drs. Irvine McQuarrie, Minneapolis, William G. Lennox, Boston, Meyer A. Perlstein, Chicago, Stanley Gibson, Chicago, Helen B. Taussig, Baltimore, Benjamin M. Gasul, Chicago, Clement A. Smith, Boston, Edith H. Lincoln, New York, Paul Gyorgy, Philadelphia, Daniel C. Darrow, New Haven, Conn., Henry G. Poncher, Chicago, Joseph Stokes, Philadelphia, Sidney Farber, Boston, and Louis K. Diamond, Boston. Communications should be addressed to: The Secretaries, Symposium on Child Health, division of medicine, University College of the West Indies, Jamaica, B. W. I.

FOREIGN

Congress of Medicine in France.—The French Congress of Medicine at Paris Oct. 15-17 will be devoted to discussions on arterial hypertension, hypersplenism, and other subjects. Information may be obtained from the Bureau des Voyages Pratiques Exprinter, 26, Avenue de l'Opera, Paris 1.

Institute for Pharmacology.—The 20th meeting of the German Institute for Pharmacology (located in Dusseldorf) will be held in Bonn, Oct. 4-7. Topics for discussion will be "New Methods of Stabilizing the Nervous System and the Metabolism" and "Blood Coagulation." Information may be obtained from Prof. H. F. Zipf, secretary of the Pharmacological Institute, Reuterstr. 2 b, Bonn, Germany.

Meeting on Blood Transfusion.—The International Blood Transfusion Society will hold its transfusion days, Sept. 12-13, at the Transfusion Centre, Geneva, Switzerland. On Saturday there will be a symposium on "Plasma Substitutes" and on Sunday a symposium on "New Concepts of Pharmacodynamics of the Shock (So-Called Refrigeration)." For information apply to the Centre de Transfusion Sanguine, Hôpital Cantonal, Geneva.

Cobalt Bomb for Italy.—The first Canadian-made "cobalt bomb" to help fight cancer in Europe, which was recently exhibited at the International Congress of Radiology in Copenhagen, Denmark, has been sent for installation to a hospital in Trento, Italy. It is reported that the cost of importing slightly more than one ounce of radioactive cobalt and the 22 tons of protective and control machinery that accompanied it was 67 million lire ($107,000). The American Mutual Security Agency contributed nearly half the cost, and Italian authorities and public subscriptions paid the rest.

Congress of Otorhinolaryngology.—The 51st French Congress of Otorhinolaryngology will hold its session at the Faculty of Medicine of Paris, Oct. 26-29 under the presidency of Dr. Louis Leroux of Paris, with Prof. Leon Binet, dean of the Faculty of Medicine of Paris, as honorary president. Topics for discussion include "Present Facts of the Physiology of Hearing and Their Clinical and Surgical Applications" and "New Acquisitions of Radio-otology." During the congress, morning operative sessions will be held at various hospitals. For information address: Dr. Henri Flurin, Cauterets, or Dr. Henry Guillon, 6, Ave MacMahon, Paris (7e).

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec. 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct. 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 10-12. Dr. William F. Mengert, 2211 Oak Lawn Ave., Dallas, Texas, Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9 Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Dental Association, Cleveland, Sept. 28-Oct. 1. Dr. Harold Hillenbrand, 222 E. Superior St., Chicago 11, General Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15 Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Medical Writers' Association, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Fall Meeting, Yale University, New Haven, Conn., Sept. 7-9. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P. Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 29-Oct. 2. Mr. Harvey T. Stethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Constantinian Society, Battery Park Hotel, Asheville, N. C., Oct. 18-21. Dr. C. F. Shook, Medical Director, Owens-Illinois Glass Company, Toledo 1, Ohio, Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14. Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

District of Columbia, Medical Society of the, *Hotel Statler*, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington 6, Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Gulf Coast Conference on Industrial Health, Shamrock Hotel, Houston, Tex., Oct. 1-3. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex., Co-Chairman.

Indiana State Medical Association, French Lick, Oct. 19-21. Mr. James A. Waggener, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Sept. 28-Oct. 1. Dr. W. H. Algie, 825 North 7th Street, Kansas City, Kans., Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Sept. 22-24. Dr. Bruce Underwood, 620 South Third St., Louisville 2, Secretary.

Michigan State Medical Society, Pantlind Hotel and Civic Auditorium, Grand Rapids, Sept. 23-25. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Midwestern Section of American Federation for Clinical Research, Congress Hotel, Chicago, Oct. 29. Dr. Robert J. Glaser, 600 S. Kingshighway Blvd., St. Louis 10, Secretary.

Mississippi Valley Medical Society, Springfield, Ill., Sept. 23-25. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Northern Hotel, Billings, Sept. 17-20. Mr. L. R Hegland, 104 North Broadway, Billings, Executive Secretary.

National Gastroenterological Association, Hotel Biltmore, Los Angeles, Oct. 12-17. Dr. A. Xerxes Rossien, 1819 Broadway, New York 23, Secretary.

Neurosurgical Society of America, The Broadmoor, Colorado Springs, Colo., Sept. 23-27. Dr. C. D. Hawkes, 22 North Manassas St., Memphis 5, Tenn., Secretary.

Nevada State Medical Association, Carter Hotel, Elko, Sept. 24-26. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New England Obstetrical and Gynecological Society, Hotel Somerset, Boston, Oct. 28. Dr. Carmi R. Alden, 270 Commonwealth Ave., Boston, Secretary.

New Hampshire Medical Society, Equinox House, Manchester, Vt., Oct. 4-6. Dr. Deering G. Smith, 44 Chester St., Nashua, Secretary.

North Pacific Society of Internal Medicine, Harrison, B. C., Canada, Sept. 18-19. Dr. Clarence C. Pearson, 1115 Terry Ave., Seattle 1, Wash., Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Texas, Sept. 16. *Dr. C. H. Wilson*, 1300 Eighth St., Wichita Falls, Texas, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Oct. 26-29. Miss Alma F. O'Donnell, 512 Medical Arts Bldg., Oklahoma City 2, Executive Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 26-30. Miss Irene Rau, 1031 Medical Arts Bldg., Omaha 2, *Executive Secretary*.

Oregon State Medical Society, Heathman Hotel, Portland, Oct. 14-17. Dr. Charles E. Littlehales, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 21-24. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Regional Meetings, American College of Physicians:

- North Dakota, Fargo, Sept. 12. Dr. Robert B. Radl, 221 Fifth St., Bismarck, Governor.
- Arkansas-Oklahoma, Tulsa, Okla., Sept. 19. Dr. Wann Langston, 117 North Broadway, Oklahoma City 2, Governor.
- Western New York, Syracuse, Oct. 9. Dr. E. C. *Reifenstein*, 109 South Warren St., Syracuse 2, Governor.
- Ohio, Dayton, Oct. 9. Dr. Charles A. Doan, Ohio State University College of Medicine, Columbus 10, Governor.
- Montana-Wyoming, Missoula, Mont., Oct. 9-10. Dr. Harold W. Gregg, 127 West Park Street, Butte, Mont., Governor.
- Southeastern—Cuba, Alabama, *Florida*, Georgia, *South Carolina*—St. Simons, Sea Island, Ga., Oct. 16-17. Dr. Carter Smith, 384 Peachtree St. N.E., Atlanta 3, Ga., Chairman.

South Central Branch, American Urological Association, Kansas City, Mo., Sept. 20-23. Dr. Rex E. Van Duzen, 721 Medical Arts Bldg., Dallas, Texas, Chairman.

Southern Medical Association, Municipal Auditorium, Atlanta, Ga., Oct. 26-29. Mr. C. P. Loranz, 1020 Empire Bldg., Birmingham 3, Ala., Secretary.

Southwestern Medical Association, El Conquistador Hotel, Tucson, Ariz., Oct. 29-31. Dr. C. C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

Southwestern Surgical Congress, Hotel Utah, Salt Lake City, Sept. 21-23. Dr. C. R. Rountree, 1227 Classen St., Oklahoma City 3, Secretary.

Tennessee Valley Medical Assembly, Read House Hotel, Chattanooga, Sept. 28-29. Dr. William G. Stephenson, 612 Medical Arts Bldg., Chattanooga 3, President.

U. S. Chapter, International College of Surgeons, Waldorf-Astoria, New York, Sept. 13-17. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical *Association*, *Salt Lake City*, Sept. 10-12. Dr. Homer E. Smith, 42 South Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Equinox House, Manchester, Oct. 4-6. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

Virginia, Medical Society of, Hotel Roanoke, Roanoke, Oct. 18-21. Mr. Robert I. Howard, 1105 W. Franklin St., Richmond 20, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 13-16. Dr. Bruce Zimmerman, 338 White-Henry-Stuart Bldg., Seattle 1, Secretary.

Western Orthopedic Association, Sun Valley, Idaho, Oct. 5-8. Dr. Forrest L. Flashman, 1301 Spring St., Seattle 4, Secretary.

Wisconsin, State Medical Society of, Hotel Schroeder, Milwaukee, Oct. 5-7. Mr. Charles H. Crownhart, 704 East Gorham St., Madison 3, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

Interim Meeting, Aero Medical Association, University of Brussels Medical School, Brussels, Belgium, Sept. 24-27. Dr. Andre Allard, Medical Director of SABENA, 145 Rue Royale, Brussels, Belgium, Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954 Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of the European Society of Haematology, *Amsterdam*, Holland, Sept. 8-12. Dr. M. C. Verloop, Maliesingle 15, Utrecht, Holland, Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, *1954. Prof. C. Plavsic, Zeleni Venac* 1, Belgrade, Yugoslavia, Secretary General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U.S.A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental *Health*, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Microbiology, Rome, Italy, Sept 6-12. For information write: Dr. V. Puntoni, Citta Universitaria, Rome, Italy.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Paediatrics, Havana, Cuba, Oct. 12-17. Prof. Felix Hurtado, 5a Avenue 124, Miramar, Havana, Cuba President.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, *International Union* of Scientific Psychology, Eno Hall, Princeton *University*, *Princeton*, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Leprosy Congress, Madrid, Spain, Oct. 3-10. Dr. Felix Contreras, Moreto 15, Madrid, Spain, Secretary.

International Neurological Congress, Lisbon, Portugal, Sept. 7-12. Prof. Almeida Lima, Avenida do Brazil 53, Lisbon, Portugal, Secretary-General.

International Office of Documentation of Military Medicine, Rome, Italy, Oct. 14-18. Colonel Medecin Prof. A. Campana, Office of the Ministero della Difesa-Esercito, Rome, Italy, Secretary.

International Society for the Study of Biological Rhythms, Basle, Switzerland, Sept. 18-19. For information write: Prof. Dr. F. Georgi, Neurologische Universitats-Poliklinik, Socinstrasse 55, Basle, Switzerland.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: *Secretariat of the Journees*, 12, *rue Pierre-Geofroix, Colombes* (Seine) France.

Latin American Congress of Obstetrics and Gynecology, Buenos Aires, Argentina, Oct. 26-31.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., *Mexico, Feb. 28-March 4, 1954.*

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan American Medical Women's Alliance, Beckman Towers Hotel, New York, N. Y., Sept. 24-Oct. 1. Dr. Ina Marsh, 140 Linwood Ave., Buffalo, N. Y., U. S. A., Registration Chairman.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

World Congress of the World Confederation for Physical Therapy, London, England, Sept. 7-12. Miss M. J. Neilson, Chartered Society of Physiotherapy, Tavistock House, South, Tavistock Square, London, W.C.1, *England, Secretary.*

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Alaska:* Anchorage and Juneau, Sept. 7. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 22-23. *Endorsement.* Phoenix, Oct. 24. Executive Secretary, Mr. Robert Carpenter, 401 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Reciprocity.* Denver, Oct. 13. Final date for filing application is Sept. 14. *Examination.* Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 10-11. *Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.*

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Sept. 14. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: Chicago, Oct. 6-8. Superintendent of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Iowa:* *Examination.* Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination.* Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 14-16. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Minnesota:* Minneapolis, Oct. 20-22. Sec., Dr. E. M. Jones, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Missouri: Kansas City, Oct. 22-24. Ex. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: Helena, Oct 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* Reno, Oct. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Hampshire: Concord, Sept. 9. Sec., Dr. John S. Wheeler, 107 State House, Concord

New Jersey: *Examination.* Trenton, Oct. 20-23. Sec., Dr. E. S. Hallinger, *28 W. State St., Trenton.*

New Mexico:* Oct. 12-13, Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Sante Fe.

New York: *Examination.* New York, Syracuse, Buffalo and Albany, Oct. 6-9. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

North Carolina: *Reciprocity.* Asheville, Oct. 12. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, December. *Reciprocity.* Columbus, Oct. 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Reciprocity.* Portland, Oct. 16-17. Sec., Dr. Wilmot C. Foster, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Oct. 1-2. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity. Columbia, Sept. 21. Sec., Mr. N. B.* Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 30-Oct. 1. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

West Virginia: Charleston, Oct. 19. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Reciprocity.* Madison, October. *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: Cheyenne, Oct. 5. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 15. Sec., Mr. Herbert D. Rhodes, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 6-7. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 9-10. Sec., Dr. Esther B. Starks, *1459 Ogden St., Denver 18.*

Connecticut: *Examination.* New Haven, Oct. 10. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 19-20. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Iowa: *Examination.* Des Moines, Oct. 13. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 9-10. Sec., Mrs. Ann Baker, 410 W. Allegan St., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska: *Examination.* Omaha, Oct. 6-7. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada: *Examination.* Reno, Oct. 6. Sec., Dr. Donald G. Cooney, Box 9005, University Station, Reno.

New Mexico: *Examination.* Santa Fe, Oct. 18. Sec., *Mrs. Marguerite* Cantrell, Box 1592, Santa Fe.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 23-24. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* Dallas and Galveston, October. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 19. Final date for filing applica*tion is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is* Nov. 27. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

DEATHS

Boothby, Walter Meredith ⊕ Albuquerque, N. Mex.; born in Boston July 28, 1880; Harvard Medical School, Boston, 1906; practiced surgery in Boston from 1909 to 1916; in charge of metabolism and respiration laboratories at the Peter Bent Brigham Hospital in Boston from 1913 to 1916; instructor in anatomy from 1910 to 1916 and lecturer on anesthesia at his alma mater from 1914 to 1916; entered the Mayo Clinic in Rochester, Minn., as head of the section on metabolism in November, 1916; later became an assistant professor in medicine, associate professor in medicine, and professor of experimental metabolism at the Mayo Foundation, where he organized the aeromedical unit for research in aviation medicine; became head of the section on aviation medicine and research at the Mayo Foundation in January, 1942; in August, 1948, was made an emeritus member of the staff, at which time he became guest professor engaged in research in aviation medicine at the Institute of Physiology, University of Lund, Sweden; in 1949 was named consultant to the Swedish Committee on Naval and Aviation Medicine; while abroad he also appeared as guest lecturer at the universities of Aarhus, in Denmark, and Oxford and Cambridge, in England; in 1950 joined the professional staff of the school of aviation medicine in Randolph Field, San Antonio, Texas, as research adviser, and later became associated with the Lovelace Foundation for Medical Education and Research as head of the respiratory laboratory; in 1952 was awarded the Order of the Commander of the North Star by the Crown of Sweden in recognition of his work in helping to establish an aeromedical laboratory in Sweden several years before; during World War I served with the American Expeditionary Forces in France for 22 months as captain and major in the medical corps; was assigned for the greater part of the time to the Gas Defense Service and was also at the front as chief of the surgical team for the St. Mihiel and Argonne battles; specialist certified by the American Board of Internal Medicine; an Associate Fellow of the American Medical Association and the Institute of Aeronautical Sciences; member of the Minnesota State Medical Association, American Physiological Society, American Society of Biological Chemists, American Society for Clinical Investigation, Society for Experimental Biology and Medicine, American Institute of Nutrition, American Society for Experimental Pathology, American Society for Pharmacology and Experimental Therapeutics, Central Society for Clinical Research, Association of American Physicians, Alumni Association of the Mayo Foundation, and Sigma Xi; one of the original fellows of the Aero Medical Association of the United States; fellow of the American College of Physicians and the American College of Surgeons; as joint recipient of the 1939 Collier Trophy, he was cited by President Roosevelt for his contribution to aviation medicine in general and research on pilot fatigue in particular; died July 4, aged 72, of acute coronary thrombosis.

Boys, Charles Edwards ⊕ Kalamazoo, Mich.; born in Grenola, Kan., April 18, 1875; Northwestern University Medical School, Chicago, 1903; fellow of the International College of Surgeons and the American College of Surgeons; member of the House of Delegates of the American Medical Association from 1913 to 1929; veteran of the Spanish American War; during World War I a member of the city draft board and during World War II a member of the selective service area appeals board; formerly city health officer: affiliated with Borgess Hospital and the Bronson Methodist Hospital, where he died July 7, aged 78, of cerebral hemorrhage.

Glatt, Morris Arthur ⊕ Beverly Hills, Calif.; born in Russia in 1890; Loyola University School of Medicine, Chicago, 1917; assistant clinical professor of otolaryngology at College of Medical Evangelists, Loma Linda and Los Angeles; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; formerly practiced in Chicago, where he was on the faculty of his alma mater, and affiliated with Illinois Eye and Ear Infirmary and Mount Sinai, Norwegian American, American, and Garfield Park Community hospitals; died in Temple Hospital, Los Angeles, July 19, aged 63, of cerebral hemorrhage.

Boland, Matthew Joseph ⊕ Reading, Pa.; born in Harrisburg, Pa., March 23, 1904; Georgetown University School of Medicine, Washington, D. C., 1931; fellow of the American College of Surgeons; past president of the Berks County Medical Society; president of the Reading-Berks Tuberculosis and Health Association; served during World War II; formerly medical supervisor of parochial schools in Reading and a member of the Berks County Board of Public Assistance; chief of surgical service at St. Joseph's Hospital; died July 16, aged 49, of carcinoma of the right lung.

Wolin, David ⊕ Rochester, N. Y.; Jefferson Medical College of Philadelphia, 1914; associate in pediatrics, University of Rochester School of Medicine and Dentistry; specialist certified by the American Board of Pediatrics; an Associate Fellow of the American Medical Association; member of the American Academy of Pediatrics; served during World War I; past president of the Rochester Pediatric Society; affiliated with Highland Hospital; served as consultant pediatrician at the Rochester General Hospital; died July 3, aged 61, of coronary occlusion and polycythemia.

Pettit, Roswell Talmadge ⊕ Ottawa, Ill.; Rush Medical College, Chicago, 1913; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; served during World War I; in 1940 was appointed member of the advisory board, division of cancer control, Illinois State Department of Health; on the staff of the Ryburn Memorial Hospital; at one time medical director of the Ottawa Tuberculosis Sanatorium; died June 27, aged 68, of coronary thrombosis.

Arnett, James Horatio ⊕ St. Petersburg, Fla.; Temple University School of Medicine, Philadelphia, 1911; member of the Medical Society of the State of Pennsylvania; died in Veterans Administration Center in Bay Pines May 22, aged 85, of encephalomalacia.

Arnold, Burt G., Bradenton, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1893; died May 20, aged 86, of coronary thrombosis.

Aubin, Alexander, Minneapolis; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Canada, 1902; died in St. Cloud, Minn., June 26, aged 80, of bilateral lobular pneumonia.

Bagwell, Barnum Williams ⊕ Madisonville, Tenn.; Medical Department of Grant University, Chattanooga, 1904; died June 28, aged 79, of a heart attack.

Beckes, Norman E. ⊕ Vincennes, Ind.; Medical College of Indiana, Indianapolis, 1897; served during World War I; for many years secretary of the city board of health; for four terms county coroner; affiliated with Good Samaritan Hospital, where he died June 19, aged 80, of pneumonia and pleurisy with effusion.

Bell, Carl Wendell, Raleigh, N. C.; College of Physicians and Surgeons, Baltimore, 1914; past president of the Raleigh Academy of Medicine; served in France during World War I; affiliated with Rex Hospital; died in Morehead City June 29, aged 65, of coronary occlusion.

Breitenbecher, Edward Robert ⊕ Highland Park, Mich.; Detroit College of Medicine, 1907; on the staff of the Highland Park General Hospital, where he died July 5, aged 70, of cancer.

Briggs, Harry Arthur ⊕ Albany, Texas; University of Texas School of Medicine, Galveston, 1913; died June 15, aged 65.

⊕ Indicates Member of the American Medical Association.

Bryson, Howard Russell, Lancaster, Pa.; Jefferson Medical College of Philadelphia, 1898; died June 27, aged 80, of cancer.

Coate, Charles Rufus ⊕ Whittier, Calif.; Medical College of Ohio, Cincinnati, 1907; died in Good Samaritan Hospital, Los Angeles, May 27, aged 75, of coronary arteriosclerosis.

Curll, Clyde Leslie ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1902; served during World War I; on the staff of the South Side Hospital, where he died July 4, aged 79, of cerebral hemorrhage.

Dixon, Chester Darwin ⊕ Santa Monica, Calif.; University of Nebraska College of Medicine, Omaha, 1926; served during World War II; on the staff of the Santa Monica Hospital; died April 11, aged 51, of myocardial infarction and arteriosclerosis.

Dougherty, William Sylvester ⊕ Portage, Pa.; Jefferson Medical College, Philadelphia, 1914; served during World War I; affiliated with Mercy and Conemaugh Valley Memorial hospitals, Johnstown, died July 5, aged 67, of coronary occlusion.

Dunton, Harold Roy ⊕ St. Albans, N. Y.; Long Island College Hospital, Brooklyn, 1904; died May 2, aged 71, of coronary thrombosis.

Eberhardt, Jacob Pope, Elberton, Ga.; Medical College of Georgia, Augusta, 1923; fellow of the American College of Surgeons; formerly affiliated with U. S. Public Health Service; died in Elberton Hospital July 1, aged 54, of cancer.

Eikenberry, Kenneth W. ⊕ Lieut. (jg) U. S. Navy, retired, Los Angeles; University of California Medical School, San Francisco, 1932; entered the U. S. Navy in June, 1931, and retired May 1, 1937; on the staff of the California Hospital; died July 15, aged 47.

Ellis, Edwin Milton ⊕ Ellsworth, Pa.; Jefferson Medical College of Philadelphia, 1901; died in the Mercy Hospital, Pittsburgh, May 14, aged 78.

Estrem, Carl O. ⊕ Fergus Falls, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; fellow of the American College of Surgeons; surgeon, St. Luke's Hospital; consulting surgeon, Fergus Falls State Hospital; died June 5, aged 73.

Farrish, George Clayton ⊕ Houston, Texas; University of Tennessee College of Medicine, Memphis, 1925; emeritus professor of clinical otolaryngology at Baylor University College of Medicine; died in St. Joseph's Hospital July 1, aged 58, of pulmonary embolism.

Foster, Robert Hale, Little Rock, Ark.; Creighton University School of Medicine, Omaha, 1906; member of the American Psychiatric Association; served on the staff of Central Louisiana State Hospital in Pineville, La.; died June 30, aged 71, of pneumonia.

Gibson, Ora James ⊕ Cape Girardeau, Mo.; Washington University School of Medicine, St. Louis, 1933; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; affiliated with St. Francis and Southeast Missouri hospitals; died May 20, aged 53.

Hayes, Milton Emerson, Youngstown, Ohio; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1895; formerly county coroner; affiliated with Youngstown Hospital; died June 26, aged 85, of renal insufficiency and carcinoma of the prostate.

Holloway, Luther William ⊕ Jacksonville, Fla.; Tulane University of Louisiana School of Medicine, New Orleans, 1914; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; formerly vice-president of the Florida Medical Association; affiliated with St. Luke's, St. Vincent's, and Riverside hospitals; died May 7, aged 64, of cerebral hemorrhage.

Hollowell, Claude Velmont, Goldsboro, N. C.; Medical College of Virginia, Richmond, 1928; died June 13, aged 48, probably of heart failure.

Merrit, William Herbert ⊕ New York City; New York Medical College, Flower and Fifth Avenue Hospitals, 1934; specialist certified by the American Board of Radiology; member of the American College of Radiology; affiliated with Boulevard Hospital in Long Island City, Mount Sinai Hospital, Montefiore Hospital for Chronic Diseases, Hospital for Joint Diseases, Beth Israel Hospital, and the Manhattan State Hospital; died July 4, aged 43, of heart failure.

Montgomery, Robert Russell ⊕ Long Beach, Calif.; University of Toronto Faculty of Medicine, 1910; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society and the American College of Allergists; affiliated with Los Angeles County Hospital, the Queen of Angels Hospital in Los Angeles, and Long Beach Community and Seaside Memorial hospitals; died May 2, aged 68, of arteriosclerotic heart disease.

Moss, Maurice H., Miami Beach, Fla.; American College of Medicine and Surgery, Chicago, 1904; died June 17, aged 72, of coronary occlusion.

Palmer, C. Harold ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1915; served during World War I; affiliated with Emanuel Hospital; died in Salem June 28, aged 62, of cerebral hemorrhage.

Pielemeier, Edward Frederick, Los Angeles; Kentucky School of Medicine, Louisville, 1894; Hospital College of Medicine, Louisville, Ky., 1895; died June 26, aged 89.

Pion, Philias Arthur ⊕ Tuscaloosa, Ala.; University of Vermont College of Medicine, Burlington, 1916; affiliated with Veterans Administration Hospital; died June 28, aged 62.

Pressman, Abraham, Los Angeles; Temple University School of Medicine, Philadelphia, 1925 and 1932; formerly affiliated with the Indian Service; died May 20, aged 54, of acute coronary occlusion.

Robinson, John Ranson ⊕ Van Nuys, Calif.; College of Physicians and Surgeons, Baltimore, 1901; member of the Oregon State Medical Society; formerly practiced in Portland, Ore., where he was affiliated with the Portland Sanitarium and Hospital; died June 22, aged 84, of myocardial infarction and arteriosclerotic heart disease.

Scott, Thomas Ewing ⊕ Colonel, U. S. Army, retired, Tampa, Fla.; University of Nashville (Tenn.) Medical Department, 1907; entered the medical corps of the U. S. Army in 1912; served during World War I; retired Sept. 30, 1945; died May 21, aged 71,

Storch, Lewis A. E., Indianapolis; Medical College of Indiana, Indianapolis, 1891; died May 12, aged 84, of cerebral hemorrhage and chronic myocarditis.

Strang, David M., La Crescenta, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; died in Minneapolis June 14, aged 77, of coronary thrombosis.

Thabes, John Alois ⊕ Brainerd, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; served as a member and president of the state board of health; fellow of the American College of Surgeons; on the staff of St. Joseph's Hospital, where he died June 29, aged 80.

Tyson, William Elisha Ellicott ⊕ Detroit; University of Maryland School of Medicine, Baltimore, 1905; died June 18, aged 76, of myocardial infarction.

Waide, Arthur ⊕ Scottdale, Pa.; Physio-Medical College of Indiana, Indianapolis, 1898; died in Henry Clay Frick Memorial Hospital in Mount Pleasant June 8, aged 77.

Wier, Frank Augustus ⊕ Racine, Wis.; Ensworth Medical College, St. Joseph, Mo., 1904; died May 27, aged 74.

Williamson, Charles Hodge, West Union, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; died June 26, aged 75, of coronary thrombosis.

Wright, Paul, Dunsmuir, Calif.; Rush Medical College, Chicago, 1903; died June 25, aged 82.

GOVERNMENT SERVICES

ARMY

General Seeley Honored.—Brig. Gen. Sam F. Seeley has been awarded a certificate of commendation for his work at Walter Reed General Hospital (Army Medical Center) Washington, D. C. For the past four years he has been chief of that hospital's surgical service and director of the surgical division in the Army Medical Service Graduate School. The citation refers to him as "an able and strong administrator in directing and implementing the policies of a large, complex surgical service consisting of all the surgical subspecialties." General Seeley will leave soon for assignment to the Office of the Chief Surgeon, headquarters of the United States Army, Europe.

Institute for Hospital Administrators.—The seventh semiannual Inter-Agency Institute for Federal Hospital Administrators will be held at Walter Reed Army Medical Center, Washington, D. C., Oct. 26-Nov. 13, 1953, for hospital administrators of the Army, Navy, Air Force, Veterans Administration, Public Health Service, and Bureau of Indian Affairs.

Personal.—Col. Robert S. Anderson has been assigned as executive officer, medical section, Headquarters Second Army, Fort Meade, Md. Previously he served as professor of military science and tactics, Johns Hopkins University School of Medicine, Baltimore.

NAVY

Annual Symposiums in First and Fourth Naval Districts.—The third annual medicodental military symposium of the First Naval District will be held at the Naval Hospital, Chelsea, Mass., Oct. 12-14. Each subject will be presented by a speaker of outstanding prominence in the specialty concerned. Special sessions have been planned in medical, surgical, dental, and medical administrative fields.

The fourth annual medicodental military symposium under the auspices of the Commandant, Fourth Naval District, will be held Oct. 19-24 at the Naval Hospital, Philadelphia.

Point credits for both symposiums will be awarded eligible reserve medical department officers on the basis of one point for each day of attendance, provided sessions attended total more than two hours. Naval Reserve Medical Department officers desiring to attend either symposium should request duty orders, without pay, from the Commandant of their home naval district. Reserve medical department officers who are members of other branches of the armed forces desiring point credit for attendance must obtain authority and appropriate orders from their area commander, or Air Force Headquarters, to assure accreditation. Reserve officers will be required to register for each day's session by presenting themselves at the registration desk. Properly authenticated reports of attendance will be rendered to the appropriate branch of the armed forces.

Information about the first district symposium may be obtained from the Commanding Officer, U. S. Naval Hospital, Chelsea, Mass., and about the fourth district symposium from the District Medical Officer, Fourth Naval District, Building 4, U. S. Naval Base, Philadelphia 12.

Medical Casualties in World War II.—A revised compilation of the killed, wounded, and decorated personnel of the U. S. Navy Medical Department in World War II is currently being distributed to Navy medical department facilities and to larger medical libraries for reference purposes. The booklet lists 1,149 medical department personnel as having been killed in action. It lists by corps the name, rank, date, activity to which attached and the location of some 3,117 commissioned officers and enlisted personnel who were wounded in action. The booklet also contains 148 pages of medical department personnel who received the top 10 awards and the location of the act of gallantry for which the decoration was awarded.

Course in Naval Aviation Medicine.—The next class in Naval aviation medicine will convene at the School of Aviation Medicine, Pensacola, Fla., Oct. 5, 1953. The course is of about six months' duration, and candidates successfully completing the course will be designated as Naval Flight Surgeons. The class will be limited to 30 medical officers of the Regular Navy and Reserve of the rank of lieutenant commander and below. The Bureau of Medicine and Surgery says there is an urgent need for Flight Surgeons in the air arm of the Navy, and eligible medical officers are requested to consider this growing field of medicine as a specialty for their career. Duty with aviation units affords general medical practice in addition to opportunities for practice in various specialty fields including otolaryngology, ophthalmology, physiology, psychiatry, and research. Medical officers desiring to enroll should apply to the Chief of the Bureau of Medicine and Surgery (Aviation Medicine Division) and should include in the request the following agreement of obligation: "I agree to remain on active duty for one year following completion of the course or for six months beyond my obligated service, whichever is longer."

AIR FORCE

French Medals Awarded.—The highest award of the French Air Force Medical Service, a gold Medal of Honor, has been presented to Major Gen. Harry G. Armstrong, Surgeon General of the U. S. Air Force. At the same time Brig. Gen. Otis O. Benson Jr. was awarded a Medal of Honor of the second class. Similar decorations also went to Brig. Gen. William J. Kennard of SHAPE headquarters and to Col. George B. Green, medical assistant to the air attaché in Paris. The presentations were for assistance rendered by all four officers to aviation medicine in France. It is the first time that the top decoration for aeromedicine in France has been given to an officer of any other nation.

Careers in Aviation Medicine.—The advanced class in aeromedicine of 10 medical officers graduated at the School of Aviation Medicine, Randolph Field, Texas, July 18. The class was a select group chosen for training in the more advanced techniques of aviation medicine. They are surgeons who wish to make a career of this specialty. Six have received orders assigning them to Johns Hopkins University in Baltimore for a further year of study. Three are rated Air Force pilots as well as doctors of medicine, who have taken their second year at Johns Hopkins. They are being assigned to the Tactical Air Command for residency training in aviation medicine.

Graduation at Air Force School.—On August 14 at the Air Force School of Aviation Medicine, Randolph Field, Texas, 115 student officers graduated. Col. Walter A. Carlson, surgeon of the Air University Command, of which the School of Aviation Medicine is a part, delivered the graduation address. A background of medical experience distinguishes the class. Major John A. Schilling, who will remain at the school as head of the department of surgery, was a former assistant professor at the University of Rochester. Capt. James P. Hammersten, also assigned to the school to head the department of internal medicine, was an assistant professor at the University of Minnesota. Capt. Edward A. Tyler taught at the University of Pittsburgh and Lieut. Leon O. Banks at Howard University. Ten of the officers have done research in various fields of medicine. More than half of those graduating had conducted their own medical practice before they entered the Air Force.

Personal.—Col. Robert J. Benford (MC), U. S. A. F., editor of the *U. S. Armed Forces Medical Journal*, will be the official representative of the Department of Defense at the fourth annual meeting of the medical editors of the world at The Hague, Sept. 7. He will also attend the interim meeting of the Aero Medical Association in Brussels, Sept. 24-27.

FOREIGN LETTERS

BRAZIL

Nontraumatic Perforation of Common Bile Duct.—Drs. Plinio Bove and Roberto Millan of the Hospital das Clinicas, São Paulo State University, reported (*Revista Hosp. clin.* 8:93, 1953) a rare case of spontaneous perforation of the common bile duct with retrocholeperitoneum and acute pancreatitis. The patient, a young woman of 21, was not aware of any trauma, and there had been no surgical operation. No stones were found on cholangiographic examination or at the operation. For some years she had had dyspeptic disturbances and right upper quadrant pains. In the last crisis, signs of peritoneal involvement appeared that led to emergency surgery. During the operation, it was possible to see a linear perforation of the common bile duct near the duodenum. The common duct was thick-walled and moderately dilated, and its mucosa showed hemorrhagic foci. A T-tube was placed in the perforation. In the postoperative course it was possible to recognize a common channel with pancreatic reflux (cholangiography) and biliary reflux (mecholyl-morphine test). There was also chronic inflammation of the common duct and the sphincter of Oddi. Cholecystectomy was done later. The biliary drainage through a Kehr catheter was maintained for 40 days, and the patient received large amounts of penicillin. In spite of this treatment the previous symptoms (pains and dyspeptic disturbances) did not disappear. This fact suggests that infection was not the principal etiological agent.

The authors believe that the main cause of this biliary disease and also of the acute pancreatitis and common duct perforation was the inflammatory process of the terminal part of the common duct. The postoperative examination by means of cholangiography and the mecholyl-morphine test showed biliary and pancreatic reflux through the papilla of Vater, causing the irritation of the epithelium by the eventual transformation of the trypsinogen into trypsin. This irritation, associated with the spasm of the sphincter of Oddi, may have led to the perforation of the common duct. They also believe that reversal of the inflammatory changes of the sphincter of Oddi, papilla of Vater, and the terminal part of the common duct may be obtained by delayed common duct drainage in about 50% of cases. When this treatment fails, incision of the papilla of Vater is the only way to obtain a complete recovery.

Mucocutaneous Leishmaniasis.—Dr. Julio Muniz of the Oswaldo Cruz Institute recently reported in *O Hospital* (43:1, 1953) the results of his experimental studies with the so-called Calle strain of Leishmania brasiliensis. This is supposed to differ from the variety reported by Dr. Barrientos who observed in Bolivia the patient from whom the material was taken. Dr. Nery Guimarães described a similar case of nodulotumoral leishmaniasis that he observed in the Amazon region of Brazil; the patient harbored a strain of the same parasite, which Dr. Guimarães also considered to be a different variety. Muniz believes that these observations illustrate the complexity of the problem of determining the causative agents of mucocutaneous leishmaniasis in man, although a great advance was made through the demonstration that the parasite causing visceral as well as cutaneous leishmaniasis in dogs is the same that produces the disease in man.

Agglutination of "Free-Living" Endamoeba Trophozoites by Human Serum.—The agglutination of "free-living" amebas has been studied by Zaubitzer (1901), Sellard (1911), Coca (1912), von Schuckmann (1920), and Heathman (1932), who tried by this means to distinguish different genera and species. To attain this aim they immunized animals through the inoculation of amebas by peritoneal or venous routes, and using the animals' serums attained various and in some cases contradictory results. The available medical literature does not contain references to the agglutinating power of human serum on "free-living" amebas, however. Drs. A. Azzi Leal and Dacio F. Amaral, of the School of Hygiene and Public Health of the São Paulo State University, reported (*Arq. Fac. hig. e saúde púb. Univ. São Paulo* 6:1, 1953), that trophozoites from cultures of Endamoeba moshkovski (a "free-living" ameba) were agglutinated by undiluted normal human serum, the agglutination being followed by the disintegration of the amebas in 15 to 45 minutes. With inactivated serum, the agglutination was observed in titers of from 1:20 to 1:320. When the material was kept in a refrigerator for 24 hours, the agglutination increased and appeared in cases in which it had been negative. No association was found between this agglutination and the presence of E. histolytica in the feces of the donors of serum. Comparing the present results with those of an investigation by the same authors (1952) in which they studied the action of the same serums on trophozoites of E. histolytica, they observed the following facts: 1. Active human serum has a disintegrative effect on both amebas. 2. The inactivated human serum agglutinates the "free-living" amebas in higher titer (1:20 up to 1:320) than E. histolytica (1:1 up to 1:40). 3. The agglutination of E. moshkovski persists and increases after 24 hours if the slides are kept at room temperature, in a refrigerator at 2 to 8 C, or in an incubator at 37 C, while under identical conditions the trophozoites of E. histolytica are destroyed.

Human Hymenolepiasis.—Dr. Dacio F. Amaral, of the School of Hygiene and Public Health, São Paulo State University, reported recently an investigation in which he stressed the importance of Hymenolepis nana in digestive abnormalities. After reviewing the cases of human parasitism by H. diminuta found in the medical literature of Brazil, he describes his work at the penitentiary of the state of São Paulo. In this study he examined the stools of 592 inmates, six times each during a period of 20 days, by the zinc sulphate flotation method. H. nana was found in 11 of the inmates, or 1.86%. The finding of H. nana in the stools was very irregular, since the first examination of the 592 subjects revealed four cases, the second examination two more cases, the third and fourth one more each, the fifth two more, and the sixth one more. In view of such irregularity, it is not known whether more tests would disclose still more cases. It is pointed out that this fact must be kept in mind if one desires to determine the exact efficiency of drugs against that worm. Results are presented of treatment of hymenolepiasis due to H. nana with chloroquine and gentian violet, showing that they were not satisfactory.

JAPAN

Yoshida Sarcoma and Free Cell Tumors.—Dr. Tomizo Yoshida, professor of pathology, department of pathology, University of Tokyo Medical School, has been awarded the Imperial Prize of the Japan Academy for 1953. The award was given at the annual assembly on May 17, in the presence of his Majesty Emperor Hirohito at the Amphitheater of the Japan Academy, Ueno Park, Tokyo. Professor Yoshida was thus honored for his contribution to the study of the peculiar type of sarcoma of the rat now called the Yoshida sarcoma, following the proposal made at the annual meeting of the Japanese Cancer Association in 1948. In the years since his discovery in June, 1943, over 30% of the cancer literature in Japan has been concerned with this tumor, an indication of its significance.

The tumor is characterized by the ability of its cells, when suspended in fluid as individually separate free cells, to proliferate in the abdominal cavity of the rat. They infiltrate

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

at the same time into surrounding tissues, resulting in massive growth that causes the death of the host in an average of 10 days.

This was first discovered in one of the 20 rats fed with o-aminoazotoluol (a carcinogenic substance discovered by Sasaki and Yoshida), followed by painting with arsenite of potassium solution on the back three times a week. Toward the end of the sixth month of the experiment a tumor was found in the scrotum; it grew rapidly within one month and was about to become ulcerated. The animal was killed on June 28, 1943, and a malignant growth was found to be widely infiltrating through the pelvic cavity to retroperitoneal tissues. In the peritoneal cavity there was a thick, milky ascitic fluid that was actually a suspension of the tumor cells. The ascitic fluid was successfully transmitted into the peritoneal cavity of normal rats.

Although Loewenthal had previously reported in 1932 a similar tumor (Ehrlic's "Ascites-Krebs"), the interest of scientists in fluid of free cell tumors actually resulted from the independent and well-controled studies of Yoshida.

Serial transplantation of the Yoshida sarcoma is performed by using a glass capillary tube, which is also useful for obtaining the tumor fluid. One droplet of the fluid is sufficient for cytological observation. The tumor fluid contains 0.5 to 1 million tumor cells per 0.001 ml. For transplantation 0.01 to 0.05 ml. of fluid containing 10 to 50 million cells is routinely used. The exact number of tumor cells in the inoculum of the Yoshida sarcoma can be easily determined by the method of counting blood cells.

Yoshida and his co-workers finally found that a single tumor cell was enough for successful transplantation. The tumor fluid was diluted until each droplet contained only one or no tumor cell. After microscopic confirmation that a droplet contained only one tumor cell, the droplet was sucked into a micropipet by means of a micromanipulator and then was blown into the peritoneal cavity through the punctured abdominal wall. The single cell transplantation was tried 125 times and was successful in 69 animals. It should be emphasized that results of all attempts using materials microscopically free from tumor cells were negative.

Mitotic forms are frequently found in smears of the Yoshida sarcoma. Each stage of cell division may be easily observed. The chromosome studies of the Yoshida sarcoma cells have been performed by Yoshida's co-workers and zoologists in this country. The number of the chromosomes varies fairly widely but 42 chromosomes, the regular number of rat germ cells, is also the most frequent number, with fluctuation between 32 and 50.

By the phase-contrast microscope it was possible to observe the entire course of a mitotic division in vitro. The average length of time for complete mitosis was approximately an hour or slightly less. The full process of mitosis of the Yoshida sarcoma has now been brought to easy observation by motion pictures taken by his research group.

The Yoshida sarcoma is most suitable for study of tumor chemotherapy, because (*a*) the cytological response can be easily, exactly, and repeatedly examined, thus serving as an indicator of the efficacy of chemicals, (*b*) direct effects of chemicals upon the tumor cells can be observed by intraperitoneal administration of materials to be tested, and (*c*) the rate of successful transplantation is as high as about 95% and the fluctuation of the life span of the tumor-bearing rats is relatively small, thus enabling easier observation of the effects.

Dr. Yoshida checked numerous compounds in collaboration with Prof. Morizo Ishidate, department of pharmacology of Tokyo University. So far nitrogen mustard and its derivatives are of the most interest in this respect. In an effort to lower the toxicity of nitrogen mustard, the N-oxide derivative of the substance was prepared; it is hydrophilic and far less toxic. The new compound was tested carefully by animal experiments and in patients with various kinds of cancer. As far as animal experiments go, it is one of the hopeful remedies. It is now provided for general use under the name of Nitromin.

The influence of Yoshida's discovery upon tumor research in Japan is limitless. It is no exaggeration to state that all aspects of tumor biology have been reinvestigated with this sarcoma: Transplantability in various strains of rats and animals of different species, histological and immunologic reactions involved in transplantation, correlations between hereditary constitution of rats and development of tumor, transplantability to chick embryo, behavior in tissue culture, respiration and glycolysis, resistance to x-rays, supersonic waves and other physical agents and all kinds of chemical substances, changes in enzymatic actions and serum protein in the sarcoma-bearing animals, cytochemical researches of the sarcoma cells, nucleic acid content of the fluid and tumor cells, paper-chromatographic studies of the tumor fluid, radioautography of the tumor fluid, radioautography of the tumor cells, and so on.

Some scientists outside Japan became keenly interested in the Yoshida sarcoma, and the samples are now maintained in the National Cancer Institute, Bethesda, Md., in Sweden and Germany. Professor Yoshida was a guest speaker of the Gorden Conference on Cancer held in New London in 1951. Dr. Yoshida and his associates are now extending their study to other types of free cell tumors and have already obtained a specimen from an experimental hepatoma of the rat.

PARIS

Psychic Disorders During Isoniazid Therapy.—On March 6, at the meeting of the Medical Society of the Paris Hospitals, R. Benda, P. Kaufmann, and J. F. Buisson reported three cases in which psychic disorders occurred between the second and the sixth weeks of treatment with isoniazid. They also noted in other patients treated with this drug some alteration of the electroencephalogram not associated with any psychic or neurological disorder. Marquezy stated that he noted a hypomanic reaction in two children who were given very large doses of isoniazid; the reaction subsided when the size of the doses was decreased. Fouquet also noted a hypomanic reaction in a man with a previous history of psychopathology after only eight days of treatment. Peron noted euphoria and excitation in some patients, and he believes that these reactions are almost identical with those observed in response to cortisone. Paraf assumed that isoniazid probably affects the diencephalon. To the contrary, Ravina contended that isoniazid has no specific action. Duroux reported on two alcoholic patients who experienced a deep disgust for alcohol after treatment with isoniazid. R. Benda and associates commented on the complexity of the problem and drew attention to the recently published work of Prof. J. Delay and associates on the favorable effect of isoniazid in patients with depression or melancholia. Therefore, caution should be observed in giving this drug to patients with a history of psychological disorders.

Studies on the Stomach.—Chiray, J. Sénèque, and S. Doubrow presented to the National Academy of Medicine an original paper on stomach pathology. In this paper, they drew attention to the histophysiological pecularity of this segment of the digestive tract. Because of their experiments, they considered the pathology of the stomach according to the action of large molecules of disintegrated albumins that penetrated the antral mucosa. According to the authors, there exist three possibilities: The first is that the large molecules, acting as reactogens, exert an influence only on the sympathetic elements of Meissner's plexus and on Auerbach's plexus, thus provoking mucosal erosion. Second, the sensitization may be restricted to the antrum itself, which might cause an ulcer following an initial Arthus' phenomenon. A third possibility is that the large molecules may provoke an endothermal reaction in the heterotopic cells, which may be the origin of an action affecting the chromosomal apparatus. This reaction may result in the beginning of development of malignancy. The authors stressed that much research is in progress in this field.

Fiftieth Anniversary of the Grancher Foundation.—The 50th anniversary of the Grancher Foundation was celebrated at the Pasteur Institute by many leaders in the medical profession. Courcoux, J. Renaults, and Armand Delille stressed the important part played by the phthisiologist Grancher in the antituberculosis struggle. The aim of the Grancher Foundation is to isolate children in good health from their tuberculous parents and to place them in the country. Every year it places 6,000 children and has branches in all departments of France. Since 1948 all children cared for by the foundation have been vaccinated with BCG. Lately, this foundation has become one of the centers for placing children who must be isolated after vaccination with BCG.

SWEDEN

Obstetric Deliveries in Hospital or at Home.—During the past two decades, a profound change has taken place with regard to the number of deliveries in hospitals and at home. At present only about 5% of all deliveries occur in the mothers' homes, whereas this was the case with about 75% 20 years ago. These figures reflect a trend that has provided the country with a network of 236 institutions ranging from fully equipped maternity and gynecologic hospitals to cottage hospitals and comparatively primitive centers in which women can be confined. Discussing this state of affairs, Dr. Ludvig Simon of the County of Norrköping reproduces several tables in *Svenska Läkartidningen* for May 29, 1953. One of the tables is concerned with the two year period 1950 through 1951. This table shows how the 222,460 confinements throughout Sweden were distributed according to whether they were at home (12,137) or in one or another of the five different types of maternity hospital. The maternal mortality was 0.069% (69 per 100,000), a record judged by international standards. The total infant mortality associated with pregnancy and confinement was 3.1%.

With these and other figures for his background, Dr. Simon raises the question: "Should an effort be made to raise the confinements in hospital from the present 95 percent to a 100 percent or should the 5 percent confinements at home be left unchallenged?" He is emphatically in favor of the former alternative, and he argues that the old system, with midwives attending mothers in their own homes, is a snare and a delusion. It may be all very well in a town where, if matters go badly at home, the expectant mother can be rushed to hospital at the last moment, but, in a thinly populated and wide area like Lapland where a journey from the mother's home to a hospital may take days, the maintenance of the old midwife system may tempt a prospective mother to remain at home for her confinement. If she knew that no provision was made for her confinement at home, she would be forced to travel to a maternity hospital soon enough for her confinement. Dr. Simon has scrutinized the conditions under which 38 confinements took place at home in the County of Norrköping in the period between 1948 and 1951. In only eight of these did the confinement take place under satisfactory economic and housing conditions. In 14, the expectant mother could not leave home because she could not get anyone to take her place there. In four others, the mothers were confined before a midwife could reach them.

Association of Bronchiectasis with Asthma.—Though certain textbooks have contained the statement that bronchiectasis is common in association with asthma, impairing the prognosis for it considerably, reliable data on this point seem to be conspicuous by their absence. Lack of systematic bronchographic examinations of asthmatic patients may well be responsible for ignorance in this matter, and, to repair it, Dr. N. Westermark and Dr. S. Wiholm of Stockholm have undertaken bronchographic examinations of 100 consecutive patients with bronchial asthma treated at the St. Göran's Hospital since 1949. The Westermark technique was followed; about 10 ml. of iodized oil (Lipiodol) was introduced after the pharynx and larynx had been anesthetized. Most of the patients had had asthma for more than 5 years, 47 of them for more than 10 years. In 18 cases, there was a history of pneumonia once or oftener, and 21 patients had had sinusitis. As many as 70 had yielded, or still yielded, purulent sputum, but genuine chronic bronchitis was present in only 5. Only in four patients was bronchiectasis demonstrable, and in each one the lesion was comparatively small, much smaller than the large and extensive lesions existing when bronchiectasis gives rise to serious symptoms. These observations suggest that asthma does not as a rule predispose the patient to the development of bronchiectasis and that the association of one disease with the other is comparatively rare. Yet in 1938, Watson and Kibler found that 90% of their patients with bronchiectasis also had asthma.

Notification of Certain Forms of Cancer in 1953.—It is hoped that Sweden will take an active part at the meeting to be held in Washington in September, 1954. The meeting has been called by the Société Internationale de Pathologie Geographique to discuss the behavior of cancer of the uterus, breasts, lungs, stomach, and liver. Professor Folke Henschen of Stockholm, the secretary of the Swedish National Committee dealing with this matter, has issued an appeal to all his colleagues to take an active part in collecting the necessary data. This committee is composed of 12 clinicians, 9 pathologists, 2 veterinary surgeons, and 3 statisticians and is presided over by Professor E. Sjövall. Physicians in Sweden have received from the Swedish Ministry of Health a questionnaire concerning the new cases of cancer diagnosed for the first time in 1953 in the above-mentioned organs. When completed these questionnaires are to be sent to the Radiumhemmet in Stockholm where they will be registered and checked to avoid duplication. The registration of cases of cancer of the liver will be undertaken by the physicians who have performed postmortem examinations. The inclusion of cancer of the liver, a rare disease in the Scandinavian countries, stresses the international character of the forthcoming meeting in Washington, for there are many subtropical and tropical countries in which this form of cancer is very common. The notification of certain forms of cancer is the first step taken in this direction in Sweden, and it may well lead to a more elaborate system of notification in the near future. In this respect, a stimulating example has already been set in Denmark where a cancer register has been dealing with all forms of cancer on a national scale for many years.

Anthropological Tests of Paternity.—Until quite recently, the only biological and laboratory test of paternity recognized by Swedish law was the blood group test. In 1949, legislation was adopted allowing the admission of certain anthropological data as evidence in disputed cases of parenthood. This law became operative at the beginning of 1950 and promises to help considerably in determining parenthood in doubtful cases. The Swedish State Institute for Human Genetics (Statens Rasbiologiska Institut) at Uppsala is often called on to give evidence in this field, and already it has provided useful information to the law courts in approximately 10 to 15% of the cases referred to it. In an account of the work of this institute in *Nordisk Medicin* for May 22, 1953, Dr. Jan A. Böök is very cautious in his estimate of the value of anthropological data in such cases. For, at present, the special anthropological studies of the Swedish population necessary for a well-balanced judgment in a given case have yet to be made. When they have, it would, in his opinion, be possible to give complete and categorical answers in most cases. Even now anthropological data, such as the color of the irises of the child, the mother, and the potential father, may clearly show which is the real father when the blood group test has left the matter in doubt. On this particular point Dr. Böök notes that at the institute no case has yet been found of a brown-eyed child being born to parents both of whom are blue-eyed. In his experience, a child must be at least 2 years old if it is to provide all the necessary anthropological data required in a disputed case.

CORRESPONDENCE

STORING AMPULS FOR SPINAL ANESTHESIA

To the Editor:—Utmost care must be taken to prevent contamination of any solution used for spinal anesthesia. Spinal anesthetic drugs are prepared in sealed ampuls and are usually sterilized by storage in a container of antiseptic solution. Severe neurological complications have been reported resulting from contamination of the anesthetic solution by the antiseptic (Nicholson, M. J., and Eversole, W. H.: *J. A. M. A.* **132**:679 [Nov. 23] 1946). This can occur if a very small crack is present in the ampul and should be detected at once. Steinberg reemphasized this danger and suggested storage of ampuls in thimerosal (Merthiolate) so the color contamination could be noted (*Anesthesiology* **11**:257 [March] 1950). Different coloring agents have been tried, and all work on the principle of antiseptic contamination giving the defective ampul a slight tint of the same color used in the antiseptic solution.

At the Massachusetts General Hospital a solution is prepared that contains fluorescein dye. It is brightly colored, but on long storage the outside of the ampul becomes stained and contamination of the contents cannot be detected until the solution is drawn into a syringe. It was believed that an indicator solution could be found that would give the contaminated ampul a color different from the color given the sterilizing solution. Preliminary tests with several indicators showed that the pH of the agents commonly used for spinal anesthesia was lower than 5.4. From the table of indicator solutions in a handbook of chemistry and physics it appeared that methyl red would change in the desired range. A test sterilizing solution was made from 95% ethanol and a saturated alcoholic solution of methyl red (pH 4.2—pink and pH 6.2—yellow) was added drop by drop until the solution was bright yellow, about a 1% solution. A trace of this sterilizing solution added to each ampul tested gave it a definite pink or red color.

Following are the spinal anesthetics that this indicator colors red: procaine hydrochloride 20%; procaine 1% and ephedrine 5%; dibucaine (Nupercaine) hydrochloride 0.25%, with dextrose 5%; piperocaine (Metycaine) hydrochloride 20%; procaine hydrochloride (Novocaine) 1%; tetracaine (Pontocaine) hydrochloride 1%; and dextrose 10%. The following vasopressors were also colored red by the sterilizing solution: methoxamine (Vasoxyl) hydrochloride; epinephrine (Adrenalin) chloride 1:1000; and phenylephrine (Neo-Synephrine) hydrochloride 1%. Ephedrine sulfate does not have a low enough pH for this indicator and takes the same color as the sterilizing solution. Ethanol, 95%, is not a solution for sterilizing ampuls, but this principle will work in any sterilizing solution used, as long as the pH is 6.2 or above or can be so adjusted by addition of sodium hydroxide.

Boston 14.

MYOCARDIAL INFARCTION

To the Editor:—For some years, it has been the teaching of eminent clinicians that the beginning of myocardial infarction coincides with the onset of acute symptoms. The literature refers to "silent infarcts" (*Am. Pract.* 4:64 [Oct.] 1949), but there is little consideration of cases in which there was eventual development of the characteristic clinical picture.

During a recent pathological study of coronary disease with Dr. J. B. Miale, I observed an interventricular septal rupture one day after onset of the acute coronary occlusion syndrome, recalling a similar case reported by Geckeler (*J. A. M. A.* **148**:1413 [April 19] 1952). Both Geckeler and Oblath, Levinson, and Griffith (*J. A. M. A.* **149**:1276 [Aug. 2] 1952) admit that well-developed myocardial necrosis is prerequisite to such rupture. According to Mallory, however, infarction necrosis of heart muscle is not well-established until the fourth day. From our own series of 84 cases, we selected the 24 hearts containing infarction more recent than the fibrotic stage. Of these, seven hearts (29%) had infarcts significantly older than the clinical histories would indicate; the discrepancy varied from two days to three weeks. Only one of the seven had myocardial damage too extensive to be compatible with recovery, and much of this was successive infarction chronologically parallel to hyperactivity of the patient. One patient had extracardiac illness that caused death, and one died of thromboembolic complications. In five there were premonitory symptoms that were not incapacitating and did not cause enough professional alarm to initiate the treatment and care usually given in cases of suspected myocardial infarction.

Out of these findings, there arise cautions that no practicing physician can afford to ignore: 1. In the patient who has had previous cardiac symptoms and who has learned to live with them in a reassured fashion, the differential recognition of chronic and acute symptoms is often obscured. 2. Myocardial injury occurring as a complication of some other illness that commands primary attention, is more likely to escape full awareness, even on the part of the clinician. For example, Wroblewski and LaDue have recently mentioned the notable absence of precordial pain in some patients suffering myocardial infarction after major surgery (*J. A. M. A.* **150**:1212 [Nov. 22] 1952). 3. Even in patients without other illness or previous coronary episode, the beginning of infarction may antedate acute symptoms by several days. Obviously, in a patient with any indications of myocardial ischemia or any of its predisposing factors, a higher index of suspicion of myocardial injury is warranted. Thus, if a patient seen supposedly at onset of the coronary occlusion syndrome is treated with the precautions that would be used for persons in the full danger stage of myocardial necrosis, complications and death may be avoided. Also, premonitory or "chronic" coronary symptoms appear worthy of more consideration than is often thought necessary.

Marshfield, Wis.

BULBAR POLIOMYELITIS

To the Editor:—The letter in the June 20, 1953, issue of The Journal (page 757) by Dr. Frank concerning the effectiveness of a well-planned approach to the management of patients with bulbar poliomyelitis deserves commendation for its clarity. At this time when we are faced with the seasonal increase in poliomyelitis, Dr. Frank's letter and the report of several thousand treated cases to which he refers (Bower, A. G., and others: A Concept of Poliomyelitis Based on Observations and Treatment of 6,000 Cases in a Four-Year Period, *Northwest Med.* [Feb., March, and April] 1950) should be required reading for all physicians treating poliomyelitis patients. The deleterious effect of hypercapnia should be well understood by both nurses and physicians.

Lest physicians in smaller communities be deterred from using the apparently complex laboratory aids outlined in Dr. Frank's letter, I wish to inform other physicians of the relative ease with which a program of laboratory guides was established in a small community hospital (Memorial Hospital of Sheridan County, Wyoming) in 1952 and to emphasize the practical value of the laboratory determinations that helped us in the management of bulbar poliomyelitis in accordance with principles outlined by Dr. Frank. Another value of such a program is the renewal of interest by other physicians in the community in the diverse metabolic disturbances in poliomyelitis and, after the poliomyelitis season, in a variety of other clinical conditions.

COUNCIL ON MEDICAL SERVICE

MATERNITY AND INFANT CARE PROVISIONS FOR SERVICEMEN'S DEPENDENTS

Genevieve W. Carter, Ph.D.
Emanuel Reznick, M.A.
and
Gloria Roman, M.A., Los Angeles

The abstract of part 1 of the study concerned with providing medical, hospital, and related services to the wives and dependents of servicemen appeared in The Journal, *June 7, 1952, page 597. Following is an abstract of part 2 of this continued study under the joint sponsorship of the Welfare Council of Metropolitan Los Angeles and the American Medical Association. This study was part of a comprehensive project from which facts were obtained as a basis for making recommendations to help solve this particular problem in medical service. The report, including the above mentioned recommendations, by the Council on Medical Service appeared in* The Journal, *June 20, 1953, page 758.*—Ed.

Application of research methods for the purpose of determining the pattern of community utilization of medical services is a recent field of endeavor in the long history of medical research. This abstract presents a summary of a research project on uses and costs of medical services. The study was conducted in two parts and originally was initiated for study of the need for an emergency maternal and infants' care program such as the one in operation during World War II.

The interest in this subject, locally as well as nationally, grew out of concern that, with the great increase in the number of persons in our armed forces, some kind of special program might be indicated for meeting the medical needs of dependents. There was a developing interest in special federal assistance to provide maternal and infant care for servicemen's dependents and considerable speculation as to the extent of need for medical care assistance among dependents.

This study, as well as the first one, was jointly financed by the American Medical Association and the Welfare Council of Metropolitan Los Angeles. Both studies were directed toward investigating the nature of the problems encountered by servicemen's wives when they were seeking and utilizing maternal and infant care services. The data for part 1 were secured through interviews with servicemen's wives residing in Los Angeles County who delivered during a selected week in January, 1952. These women were interviewed in a total of 89 hospitals and maternity homes. In a small number of cases, the interviews took place in the women's homes shortly after delivery.

Experience gained in the first study led to a clarification of the concept of need. Conclusions that describe the needs for medical care in general terms cannot serve to point up specific patterns of medical service that might be developed to alleviate the need. When need is expressed in terms of the nature of the problems or difficulties encountered when seeking and utilizing medical services, however, the data obtained can readily be translated into remedial measures.

DESIGN OF THE STUDY

The universe for part 2 was the total number of servicemen's wives living in Los Angeles County who delivered during the month of August, 1951. Most of these women delivered in hospitals located within the boundaries of Los Angeles County, but some delivered in hospitals in adjacent counties and as far away as San Diego.

The seven months intervening between the time of birth (August) and the study period (March and April) allowed for the inclusion in Los Angeles County Vital Statistics of the out-of-county births. From the universe of 286 cases, a 25% stratified random sample was selected. Visits were made in a total of 129 cases, yielding 71 completed interviews. It was anticipated that some of the women selected for interviewing would have left the area and would not be traceable. Therefore, it was necessary to construct a sampling method[1] that would allow for substitution of cases similar in essential characteristics to the lost cases. In order to get such cases it was necessary to stratify the population in terms of criteria demonstrably related to the problem under observation, i. e., in terms of problems encountered by servicemen's wives in seeking and utilizing maternity and infant care. These criteria were selected through analysis of the cases included in part 1 of the study.

An interview schedule was constructed and tested in a pilot study. Major categories covered were (1) general information on social situation of the family; (2) information on prenatal care; (3) information on hospitalization; (4) financial costs and methods of payment for prenatal, delivery, and hospital care; (5) attitudes regarding medical care and financing; (6) postpartum care; and (7) pediatric care.

Table 1.—*Pattern of Resources Used by Seventy-One Women in the Sample, Los Angeles, August, 1951*

	Type of Care			
Facility Used	Prenatal Care, %	Hospital Care, %	Post-Partum Care, %	Pediatric Care, %
1. Private Physician	54.9%	....	64.8%	43.7%
2. Private Hospital	4.2	63.4%	5.6	0.0
3. Military Facility	14.1	14.1	14.1	8.4
4. County or City Facility	12.7	22.5*	11.3	15.5
5. Combined Military and County or City Facility	1.4	....	....	1.4
6. Combined Public † Facility and Private Physician	11.3	....	0.0	28.2
7. No care	1.4	....	4.2	2.8‡
Total	100%	100%	100%	100%

* One of these women delivered twins.
† Public here includes military, county, and city facilities.
‡ One baby died three days after birth.

SUMMARY OF FINDINGS

Analysis of the data revealed three problems generally felt and expressed by the women. These problems were not equally distributed but recurred often enough for them to be considered general in the population. They were (1) financial difficulty, (2) the distance to medical facilities, and (3) lack of knowledge of community services.

Interestingly, lack of maternity medical care was not a problem for servicemen's wives in the Los Angeles area; 91.6% of the sample received prenatal care, hospitalization, and postpartum care and their infants received pediatric care. The amount of care was generally high, and care was received for the first time early in the course of the pregnancy.

Three types of facilities were available and used to varying degrees, (1) private; (2) military; (3) city or county. Table 1 shows the pattern of resource use.

1. THE PROBLEM OF FINANCIAL DIFFICULTY

In a sense, the problem of financial difficulty was a consequence of obtaining care. Since the women received care, it was necessary that they or others assume responsibility for payment. Financial difficulty was defined as (1) choice of a particular type of care for financial reasons rather than for expected standard of care and/or (2) response of yes to a question such as "Would you say you felt financial hardship during this period?" A total of 66.2% of the women satisfied one or both of these criteria in regard to hospital care, and 62% in regard to prenatal care.

From the Research Department, Welfare Council of Metropolitan Los Angeles.

[1] Carter, G. W.; Reznick, E., and Roman, G.: Maternity and Infant Care Provision for Servicemen's Dependents, Publication No. 13, Research Department, Welfare Council of Metropolitan Los Angeles, 1952, pp. 5-9.

The expressions of financial difficulty had as their background the monthly income available and costs of maternity care. Table 2 shows the distribution of monthly incomes available[2]; 67.6% of the women received monthly incomes of $150 or less.

TABLE 2.—*Monthly Income Available During Prenatal Period for Seventy-One Women in the Sample, Los Angeles, August, 1951*

Prenatal Monthly Income	Percentage
$0-$150	67.6%
$151-$250	21.2%
Over $250	11.2%
Total	100.0%

Table 3 shows total charges for maternity care. Included are charges for all care received by the woman. Charges for pediatric care do not appear here. Almost one-quarter, or 24.0%, were charged more than $250 for maternity care. Over one-half, or 59.2%, were charged more than $150.

The women used several alternatives to reconcile the discrepancy between income and costs. One major group sought subsidized maternity care. Table 1 shows that 43.7% received some subsidized prenatal care and 36.6% subsidized hospital care. Another large group sought private care but paid for it on an installment basis. Half the women paid for private prenatal care in installments; however, payment for private hospitalization in installments was less frequent.

Somewhat less important was the use of supplemental funds such as savings or other income, insurance, or income from employment. Only 5.6% had even partial insurance coverage. Income from employment was used to pay part of prenatal costs in 9.9% of the cases and hospital costs in 8.5%. Subsidies were received by 47.9% of the women for their living expenses as well as/or for medical care. These women shared households and contributed less than their full share of expenses or lived in independent households and received regular contributions from parents.

2. THE PROBLEM OF DISTANCE TO MEDICAL FACILITIES

The second problem, distance, occurred often when a woman sought military care as an alternative to private care. The closest military hospital was approximately 50 miles to the north. The best known military hospital, approximately 100 miles south of the Los Angeles area, was at Camp Pendleton.

TABLE 3.—*Total Charges for Maternity Care to Seventy-One Women, Los Angeles, August, 1951*

Total Charges	Percentage
$0-$50 *	29.6%
$51-$100	1.4%
$101-$150	7.0%
$151-$200	16.9%
$201-$250	18.3%
$251-$300	8.5%
Over $300	15.5%
No information	2.8%
Total	100.0%

* Includes those women who received free prenatal care at military or public health department clinics and made token payment for care in military hospitals ($1.75 per day for rations) or were not billed for care at the Los Angeles County Hospitals.

The attitude of the women toward military hospitalization as distinct from county hospitalization was important in relation to this problem. They tended to accept military care as a real alternative available to them, but to define county hospital care as "for charity cases" and therefore not usually acceptable or available to them. Table 4 shows the percentage of women using the various types of care who indicated that distance to the military facilities was a deterring factor in their use.

Distance was undoubtedly made even more important because of the general inexperience of these women; 76.1% were primiparas, and 32.4% were 19 years of age or younger. They were not wives of professional soldiers; 42.3% of their husbands had been in the armed forces one year or less at the time of hospitalization. In 45% of the cases the husbands were in the three lowest pay grades.[3] Had military hospitalization been available within the county, it might have been used by a greater percentage of the women.

3. THE PROBLEM OF LACK OF KNOWLEDGE OF FACILITIES

There were four possible alternatives for prenatal care: (1) private physicians, (2) private hospital clinics, (3) city or county public health department clinics, and (4) military clinics. There were three possible alternatives for hospital care: (1) private hospitals, (2) military facilities, and (3) county hospitals. In some cases one or more of these was not a real alternative, since the women were unaware of its existence or learned of its existence relatively late in the prenatal period. Table 5 shows the distribution of lack of knowledge of military and/or city and county resources for maternity care.

TABLE 4.—*Percentage of Women Who Indicated Distance to Military Facility Was a Deterring Factor in Its Use*

Facility Actually Used	Percentage Deterred by Distance	
	For Prenatal Care	For Hospitalization
Private	45.2%	51.5%
Public Health Departments	88.9%	68.8%
Military	70.0%	70.0%

TABLE 5.—*Distribution of Women Who Lacked Knowledge of Military and/or Public Health Department Resources*

Facility Not Known of	Percentage Lacking Knowledge	
	Prenatal Care	Hospital Care
Military facilities	16.9%	16.9%
Public health department facilities	25.4%	14.1%

About one-fourth, or 25.4%, of the women could not have chosen public health department facilities and 16.9% could not have chosen military facilities for prenatal care, since they were unaware of their existence or availability. Likewise, 16.9% could not have chosen military hospitals and 14.1% could not have chosen county hospitals. The only possible solution to this problem was to choose from the facilities that were known.

OTHER ITEMS OF INTEREST

In addition to the analysis of data in terms of the three general problems, the full report[4] discusses certain specific aspects of the maternity situation. It presents data concerning (1) postpartum care, (2) pediatric care of the infant, (3) pediatric care of older children, (4) medical complications, and (5) changes in the social situation subsequent to hospitalization.

REPORT OF CASES

The following cases were selected to illustrate the kinds of problems encountered by servicemen's dependents in seeking and receiving maternity and infant care. As previously discussed, the definition of financial hardship used in this study did not rest primarily on the type of medical care received, the particular facility used, nor the objective characteristics of the patient's particular situation. Rather, it rested primarily on the woman's feelings and attitudes regarding the kind of care that she received and the problems that she encountered. This means that one woman using county hospital facilities may have been particularly disturbed about this, because she normally, given the financial resources, would have used a private physician and a private hospital. Another woman using the same facilities may have been completely undisturbed because these were the resources that she would have used in any case. The second woman's "normal" circumstances are such that they were not drastically altered by her husband's induction into the armed services. The same is true for women using private hospitals. One woman used such facilities at the cost of great self-deprivation. Her opposite, however, using the same resources, may have done so without feeling any undue financial hardship. The other two problems encountered by servicemen's dependents when seeking and securing maternity and infant care, i. e., distance from medical facilities and lack of knowledge of community resources, may also have been in evidence in some cases and not in others, although the patients used the same facilities and appeared to be in identical circumstances.

---

[2] Monthly income includes allotment, money earned from employment, and husband's pay if he was living in the household or any additional allowances if he was away from home.

[3] The data showed that women with husbands in the higher pay grades tended to choose military care as the alternative to private care; women in the lower pay grades tended to choose nonmilitary public care as the alternative to private care.

[4] Footnote 1, pp. 43-63.

The six case reports are grouped by type of hospital used. The women in the first two cases delivered in private hospitals; those in the second two cases delivered in military hospitals; and those in the third two cases delivered at county hospitals.

DELIVERY IN PRIVATE HOSPITALS

Case 1.—Background: Mrs. A. was 19 years old. Her husband, aged 22, was a private in the Army and was stationed in Germany at the time of the birth of this, her first child. He had been in the service approximately 10 months. Mrs. A.'s allotment was $85. She was not employed during her pregnancy. She lived with her sister and brother-in-law and their family during and after her pregnancy. She made no financial contribution to the household, but did all the housekeeping while her sister worked. Her allotment at time of interview was $107.50. For three weeks after her delivery, she lived in her mother's home while convalescing. At the end of that period, she moved back into her sister's household.

Medical Care: Mrs. A. had the services of a private obstetrician for her prenatal care, delivery, and postpartum care. Her first prenatal care was during the third month. She saw her doctor eight or nine times during pregnancy. Hospitalization was at a private hospital, about 35 miles from her home. Mrs. A. stayed in the hospital four days, in a ward bed. She has been seen by the obstetrician five times since delivery because of complications. The child is seen by a private pediatrician once a month.

Finances: Total cost for prenatal care, delivery, hospitalization, and postpartum care was $318. Of this, $175 was the physician's fee and $143 was hospitalization charges. The physician was paid in installments before delivery. The hospital was paid in full at the time of discharge. The charge for pediatric care amounts to $85 a year, paid in installments over a six month period.

Reasons for Choice and Attitude: Mrs. A. chose her physician because "my sister had that doctor." She "had not thought of using a public health department clinic." She definitely "would have chosen an Army facility, but Birmingham was closed and there was nothing reasonably near, Long Beach and Oceanside were much too far." She said, "If I didn't have my sister, we wouldn't have got by." She refused a blood transfusion that was recommended by her physician when she heard what the blood would cost, because "I didn't have the money." She "talked the doctor out of it." She said, "I paid the bills, but had nothing left. I had barely enough money for all the other things." All bills were paid from her allotment check. She said, "I had to take everything I had, my whole allotment—and had just nothing left, but I had to pay it and I got it all paid up."

Case 2.—Background: Mrs. B., aged 19, has lived in the Los Angeles area most of her life. Her husband, aged 22, was a sergeant in the Marine Corps, stationed about 80 miles east of Los Angeles. He had been in the service four years at the time of the birth of their first child. During the pregnancy, Mrs. B. lived with her husband in a trailer. She came into Los Angeles for her medical care and for the delivery of the child. Since the birth of the child, Mr. B. has been discharged from the Marine Corps. They are now living in the Los Angeles area in an independent household. Mrs. B. worked during the first two months of her pregnancy but has not been employed since. During the pregnancy she received an allotment of $127.50 per month.

Medical Care: Mrs. B. had the services of a private obstetrician for her maternity care. She was seen by the physician twice a month during her pregnancy. She came to Los Angeles for these visits—a distance of approximately 80 miles. Hospitalization was five days in a semiprivate room at a small hospital. Since the birth of the child there has been one postpartum examination. The child was first under the care of a private pediatrician and is now receiving care from a private general practitioner.

Finances: The total cost for prenatal, delivery, hospitalization, and postpartum care was $220. Of this, the physician's fees were $120. The hospital care cost $100. The physician was paid $50 through Blue Cross insurance. The remaining $70 was borrowed from Mrs. B.'s mother, and was paid to the physician in a lump sum after delivery. The hospital was paid in a lump sum at time of discharge. The $100 for this bill also was borrowed from Mrs. B.'s mother. The pediatric care has been paid for at each visit from Mr. B.'s salary. Mrs. B. did not know what the total cost had been to date.

Attitude and Reasons for Choice: Mrs. B. used the services of a private obstetrician because "my sister-in-law had her two babies with him." She said she didn't use the facilities at the Marine base because "I didn't want to, because you see one doctor in X, then they rush you to Y for your delivery and a different doctor takes care of you then." She didn't know about the county or city public health department clinics. She said "I might have used them; my husband may not have felt good about it, but it certainly would be a big help to some of the girls. Probably the care is just as good, too." She felt that the prenatal care she had received was excellent. She chose a private hospital for delivery rather than a military facility, because she thought "military care is not too good. You don't get any individual attention. They aren't careful." Though apparently she would have considered using a public health department clinic, the notion of a county hospital was something very different. She said, "Oh, my mother wouldn't want me to go there." In terms of the total financial situation, Mrs. B. said, "We were all right, we were very lucky compared to the other girls. We paid off my mother when my husband got his money from the State" (his veteran's bonus).

DELIVERY IN MILITARY HOSPITALS

Case 3.—Background: Mrs. C. was a 23-year-old woman who had lived in the Los Angeles area for two years at the time of the birth of her first child. Her husband, 27, a seaman first class in the Navy, was stationed in Virginia. During her pregnancy, she received an allotment of $85 a month. She worked until three weeks before the birth of the baby, earning approximately $45 a week. She shares a household with a roommate, paying half the rent and buying her own food. She has moved once since the birth of her child. Her husband is still in the service. She now receives an allotment of $147 and has not worked since the birth of the child.

Medical Care: Mrs. C. used the services of a private obstetrician and a Navy infirmary. She began her prenatal care with the obstetrician in her second month and continued with this physician through her eighth month. She then made one visit to a Navy infirmary for her final check-up. Delivery and hospitalization for four days were at a Navy hospital. She was examined at six weeks postpartum by a private gynecologist, and her baby is under the care of a private pediatrician.

Finances: Cost for prenatal care was $55 for the private physician. There was no charge for delivery, and only token payment ($1.75 per day) for hospitalization. Postpartum care cost approximately $10 plus $4 for each injection treatment.

Attitudes and Reasons for Care: Mrs. C. indicated she chose a private obstetrician for care because "I was sick at the beginning of my pregnancy and couldn't wait for a clinic appointment at the Navy infirmary." She didn't know of the existence of private hospital clinics, nor did she know of the existence of city or county public health department clinics.

She said she would have gone to the Navy infirmary, if she "hadn't had to wait half a day." She indicated she had first made an appointment at the Navy infirmary, waited three hours to see a physician, and then cancelled the appointment. She was "too sick to wait." As to her choice of the Navy hospital for hospital care, she said, "It was a matter of finances. I didn't have the money to go any place else." She would have gone to a private hospital if she had had the money. She said, "My father died just before the baby came and I used what I saved from my salary as well as my allotment to pay for his funeral." She did not know of the existence of county hospital facilities. She thought her care with her private doctor was good. She also said, "The only thing I didn't like about the Navy infirmary was the waiting." She was pleased with her hospital care: "It was awfully nice. The food was good and the treatment was very nice." As to the financial situation, she "didn't feel her doctor had charged her too much," but she did feel financial hardship "because of the extra expenses of (her) father's funeral."

Case 4.—Background: Mrs. D., aged 20, has lived in the Los Angeles area for approximately one year. At the time of the delivery of her first child her husband was a petty officer in the Navy, stationed in the Los Angeles area, and had been in the service for one and one-half years. Mrs. D. was living in an independent household with her husband, who was home most evenings. Her allotment was $127.50. This, plus her husband's income, made a total monthly income af approximately $220. Mrs. D. was not employed during her pregnancy. There has not been any change in the social situation since the birth of the child.

Medical Care: Mrs. D. used the services of a Navy infirmary for her prenatal and postpartum care and for her child's pediatric care. She delivered at a Navy hospital. Prenatal care began in the sixth month. She visited the infirmary once a month until the last two months, at which time she went every two weeks until the last month. During her last month, she visited the infirmary weekly. She was hospitalized for 10 days in a ward. Mrs. D. had a postpartum check-up at the Navy infirmary three months after her delivery. The child was seen for pediatric care at the Navy infirmary 15 days after his birth and then monthly.

Finances: There were no charges for maternity or pediatric care in this case, except a token payment ($1.75 per day) for hospitalization.

Attitude and Reasons for Choice: Mrs. D. said she chose the Navy infirmary for prenatal care because "I'm in the Navy and I'm entitled to that care." "Some of the guys are uppity and said they never would send their wives to the Navy infirmary but I don't believe in that." She had tried to get an appointment at the infirmary as soon as she arrived in Los Angeles when she was four months pregnant; however, she could not get an appointment until her sixth month. She did not know of the existence of public health department clinics in the Los Angeles area, but said "I would not have gone anywhere else, when I could get free care through the Navy." Regarding prenatal care, she "had no complaint about it except that you have to wait, and it's a long way to go." In regard to her hospital care, she chose a Navy hospital because "it was free." It never occurred to her to use a private hospital and she didn't know of the existence of county hospital facilities. She said, "It was far to go, but I had very good care. I had a lot of trouble, and they were very nice."

DELIVERY IN A COUNTY HOSPITAL

Case 5.—Background: Mrs. E. was a 20-year-old woman who had lived in the Los Angeles area five months at the time of the birth of her first child. Her husband was a corporal in the Army, stationed at a camp in northern California. He had been in the service nine months. Mrs. E. lived with her sister and her sister's family. She contributed about $40 a month to the household. Her allotment during her pregnancy was $85. She worked during the first three months of her pregnancy as a waitress, earning approximately $32 a week. Mrs. E. moved into her mother's household after the birth of the child and lived there about five months, then moved back into her sister's household. With the birth of her child, her allotment was increased to $127.50. Her husband is now stationed in Korea and "I think he is a sergeant." Mrs. E. worked for two months after the birth of the child, earning approximately $55 a week. The contribution to the sister's household has remained the same.

Medical Care: Mrs. E. used the services of an Army infirmary for prenatal, postpartum and pediatric care. She delivered at a county hospital. Prenatal care began in the fourth month. Mrs. E. went to the infirmary once a month, by public transportation. She said it took approximately one hour to get there. She was hospitalized for five days, in a ward bed. She was seen at the infirmary for a postpartum examination at six weeks. The child has been taken to the infirmary approximately once a month since its birth.

Finances: Medical care at the infirmary was free. Mrs. E. has not received a bill for hospitalization.[5]

Attitude and Reasons for Choice: Mrs. E. indicated that "I could not afford private care," and that was why she chose the military facility for her prenatal care. She said, "I liked my care and only wish there had been a (military) hospital closer that I could have gone to." In addition to her prenatal care at the Army infirmary, it was necessary for her to go to a Navy hospital twice during her pregnancy, for "extra care and blood transfusion." Regarding her choice of the hospital, she said, "It was the only place I could afford to go. Private hospitals are too expensive and the military hospital was much too far. I could have never made it there on time." Her general attitude about the total maternity situation was, "It was wonderful to get everything free."

Case 6.—Background: Mrs. F., aged 24, has lived in Los Angeles all her life. Her husband, aged 23, is a private in the Army. He had been in the service approximately three months at the time of delivery. Mrs. F. received an allotment of $85. She worked until her seventh month of pregnancy as a waitress and earned $35 per week. She lived in her own apartment in a low-cost hotel during her pregnancy; her mother lived in the same hotel but they did not share quarters. Mrs. F.'s allotment was cut off at the time of the birth of her child, because her husband was AWOL. He is now waiting court martial at an Army camp. She is living on general relief, receiving $75 a month from the county. She has not worked since the birth of the child.

Medical Care: Mrs. F. used the services of a city public health department prenatal clinic. Her first visit to the clinic was during the fifth month. She went approximately every two weeks. The clinic was close enough for her to walk. Hospitalization for six days at the time of delivery was at a county hospital, in a ward. There have been no postpartum examinations since discharge from the hospital. The child has had pediatric care at a public health department clinic once a month since its birth. It had bronchitis shortly after birth and was hospitalized three days at the same county hospital.

Finances: There were no charges for prenatal, delivery, postpartum, or pediatric care. Mrs. F. has not been billed for hospitalization.

Attitudes and Reasons for Choice: Mrs. F. indicated she "could not afford a private doctor and the military clinic was too far." She said, "I would have preferred to have had my own doctor if I could have afforded it." She selected the county hospital for delivery and hospitalization "for the same reason." She indicated she was satisfied with the care she received.

---

[5] Patients in labor are eligible for admission to the county hospitals either as medically indigent residents of the county or because they are medical emergencies. Those who are dependent on a service allotment and who are or whose husbands are residents of Los Angeles County are not currently billed. They may at a later time, if an increase in their assets warrants, receive bills for the cost of care. The others are billed soon after discharge. Under state law and county ordinance, the cost of all medical care given is reimbursable and the county may attempt to recover the cost. Persons who appear to have no ability to pay are not pressed for payment.

THE LEISURE CORNER

THE FLOWERING HOBBY

A well-chosen hobby growing naturally out of innate desires, needs, and abilities makes a joyful contribution to the art of living when things go well in the practice of medicine and at the same time provides a sphere of activity to which it is possible to turn for solace when the problems of a busy medical life enlarge. High on the list of activities that can be pursued as a hobby is the ancient and enjoyable art of gardening. Raising flowers appeals to several senses and is full of rewards and surprises, for, besides the fact that it can be shared with others and thereby doubly enjoyed, its study and cultivation may also be carried as far and wide and made as specialized as the interested hobbyist wishes. Actually, horticulturists are ideal hobbyists for riding their hobby horses along garden paths and through the bypaths of suburban and metropolitan back yards, pausing to sniff graciously at the humble flower pot. To enter this kind of world, a love of flowers and plants and a bit of earth are the only equipment necessary to start the busy physician off on an interest that can lead to such highly specialized activities as the cultivation of prize-winning flowers.

Some years ago Charles Dudley Warner, the writer, expressed the belief that sooner or later an inborn love for the soil eventually makes itself known to every human being. "Mud pies," he asserted, "gratify one of our first and best instincts. Therefore, for those who ask, 'Who should attempt growing flowers?' the answer is 'Anyone who likes them well enough to take care of them.'" Since many flowers will thrive almost under any conditions if given reasonable attention, raising flowers is a pursuit suitable for physicians who reside in suburbs and rural communities and for city dwellers who are landless but not potless, or who, at best, are owners of a tiny back yard. Today more and more miniature gardens sprout in metropolitan environs; flowers need be neither confined to back yards and roofs nor limited to the restrictions imposed by indoor gardens or window boxes. Literally, a green fairyland can be the lot of the urban dweller who, by watching flowers and plants unfold their leaves and develop their blossoms, may indulge in flights of the imagination that will convey him above imaginary fields and mountainsides.

Flowers are mostly grown in gardens where, appropriately enough, they either mingle with other flowers or occupy an individual corner all by themselves. It is in home gardens that much experimental work on the propagation and growth of flowers has been carried on, and it is in precisely this milieu that the flowering hobbyist notices their virtues and their flaws. Here, the terminology of flower culture will carry the physician back to the day when he studied biology as a medical student—genes and chromosomes, pollen, fungi, viruses, and molds. There are vectors to be dealt with, and the process of hybridizing, and the breeding out of undesired traits in flowers while retaining more desirable characteristics.

Take the case of the African violet (Saintpaulia), a favorite American house plant, which grows well and blooms almost endlessly under conditions imposed by the average house dwelling, but which will not flourish so readily as to permit the disinterested person to neglect it or to lose interest in it. More than a half century ago the African violet was discovered in the hilly regions of eastern tropical Africa. From the day of its discovery, it took the horticultural world by storm, so that when in the autumn of 1946 the first African violet show was sponsored in Atlanta, Ga., the ensuing thousands of visiting violet fans required the attention of police to maintain traffic and order. Today, few persons dispute the possibilities of the African violet as a hobby plant for collectors, and at least 175 varieties appear by name in lists gathered throughout the United States.

While many plants are grown for their foliage, this is not the case of the African violet; since its native habitat is in shady nooks and in wooded places, it does not require a flood of sunshine. Indeed, too much sunshine affects foliage adversely, turning it yellow, burning the margin of leaves, or causing malformation of leaf and flower. In general, it flowers well in any light situation where brightness is somewhat diffused. The stronger the light the deeper the color tones and the greater the tendency to flower. The most satisfactory circumstance surrounding the African violet is its tolerance to the usual household heat and its ability to thrive in an atmosphere up to 75 F. A temperature less than 60 F impedes both growth and flowering. Many hobbyists have found that African violets bloom and thrive more freely if each plant is set on a pebble-filled saucer with some water in it as a ready means of humidifying the surrounding air.

African violets are easily propagated, and they multiply readily by means of division or through leaf propagation; moreover, they can be raised from seed, and from a single seed pod it is possible to obtain as many different varieties as there are seeds. Not so long ago there was but one type of Africa violet extant, a species known to the initiated as Saintpaulia ionanatha. Now there are scores. Definite strains and varieties are being grown, with purples, pinks, and whites abounding.

In the United States alone approximately 75 species of North American violets are found, several kinds having what botanists call cleistogamous flowers. These are flowers that follow the early, showy-colored blossoms of the plant and are produced on very short scapes hidden beneath the leaves and sometimes in the soil itself. Cleistogamous flowers have no petals, never open, and contain very little pollen; as they are confined wholly within the blossom, the seeds are invariably fertile. Among the commoner species of violets producing cleistogamous flowers are the round-leaf violet, butterfly violet, palm violet, and the blue marsh violet.

Numerous violets are propagated from seed, while many kinds are due to division and to spread by means of short runners. In favorable locations certain species, for example, the blue marsh violet in the garden and the sweet white violet in the woodland, tend to become obnoxious, since they seed so freely and grow so rapidly that more fragile flowers encountered by them become half smothered.

Violets are further classified into two groups: a stemless group, in which leaves and scapes rise directly from the root stock or from runners, including such specimens as birdsfoot violet, blue marsh violet, and palm violet, and a second group, having tall, leafy stems, and whose best known members are the downy yellow violet and the Canada violet. A two-colored birdsfoot violet has upper petals of rich, royal purple and lower ones of pale blue, making it probably the showiest of all violets. The birdsfoot violet belongs to the stemless species and is easily naturalized in almost any soil that is not too wet. The two-colored violet nearly always blossoms in autumn and in spring.

The butterfly violet is one of the strongest growing, most persistent members of the violet species, seeding itself so as to form a veritable ground cover. It grows from 6 to 10 inches in height; its flowers are quite large; and it varies in color from deep blue to white. The Confederate violet, consisting of blue and gray colors, is apparently a variety of this species. The palm violet derives its name from the shape of its leaves, which are large, substantial clumps a foot in height that completely cover the ground in moist or fairly dry shade. The roundleaf violet is one of the earliest wildflowers to bloom, while the downy yellow violet is a foot tall.

The sweet white violet blossoms in the spring, and the tiny white flowers on its stems are only two to three inches tall and are very fragrant. Like most violets, the leaves increase rapidly in size after blooming. The Canada violet, whose fragrant flowers are white with a purplish tinge and blossom more or less throughout the summer, grow a foot or more tall. Finally, the primrose-leaved violet derives its name from the shape of its leaves. This species thrives most satisfactorily in moist soil that contains a considerable amount of sand.

What has been said about violets applies equally well to a vast number of other flowers and plants, be they roses, orchids, irises, lilies, or camellias. All in all, an interest in flowers can easily become a hobby that consists of doing what one wants to do, rather than a fad that is pursued because other persons do it.

She said she would have gone to the Navy infirmary, if she "hadn't had to wait half a day." She indicated she had first made an appointment at the Navy infirmary, waited three hours to see a physician, and then cancelled the appointment. She was "too sick to wait." As to her choice of the Navy hospital for hospital care, she said, "It was a matter of finances. I didn't have the money to go any place else." She would have gone to a private hospital if she had had the money. She said, "My father died just before the baby came and I used what I saved from my salary as well as my allotment to pay for his funeral." She did not know of the existence of county hospital facilities. She thought her care with her private doctor was good. She also said, "The only thing I didn't like about the Navy infirmary was the waiting." She was pleased with her hospital care: "It was awfully nice. The food was good and the treatment was very nice." As to the financial situation, she "didn't feel her doctor had charged her too much," but she did feel financial hardship "because of the extra expenses of (her) father's funeral."

Case 4.—Background: Mrs. D., aged 20, has lived in the Los Angeles area for approximately one year. At the time of the delivery of her first child her husband was a petty officer in the Navy, stationed in the Los Angeles area, and had been in the service for one and one-half years. Mrs. D. was living in an independent household with her husband, who was home most evenings. Her allotment was $127.50. This, plus her husband's income, made a total monthly income af approximately $220. Mrs. D. was not employed during her pregnancy. There has not been any change in the social situation since the birth of the child.

Medical Care: Mrs. D. used the services of a Navy infirmary for her prenatal and postpartum care and for her child's pediatric care. She delivered at a Navy hospital. Prenatal care began in the sixth month. She visited the infirmary once a month until the last two months, at which time she went every two weeks until the last month. During her last month, she visited the infirmary weekly. She was hospitalized for 10 days in a ward. Mrs. D. had a postpartum check-up at the Navy infirmary three months after her delivery. The child was seen for pediatric care at the Navy infirmary 15 days after his birth and then monthly.

Finances: There were no charges for maternity or pediatric care in this case, except a token payment ($1.75 per day) for hospitalization.

Attitude and Reasons for Choice: Mrs. D. said she chose the Navy infirmary for prenatal care because "I'm in the Navy and I'm entitled to that care." "Some of the guys are uppity and said they never would send their wives to the Navy infirmary but I don't believe in that." She had tried to get an appointment at the infirmary as soon as she arrived in Los Angeles when she was four months pregnant; however, she could not get an appointment until her sixth month. She did not know of the existence of public health department clinics in the Los Angeles area, but said "I would not have gone anywhere else, when I could get free care through the Navy." Regarding prenatal care, she "had no complaint about it except that you have to wait, and it's a long way to go." In regard to her hospital care, she chose a Navy hospital because "it was free." It never occurred to her to use a private hospital and she didn't know of the existence of county hospital facilities. She said, "It was far to go, but I had very good care. I had a lot of trouble, and they were very nice."

DELIVERY IN A COUNTY HOSPITAL

Case 5.—Background: Mrs. E. was a 20-year-old woman who had lived in the Los Angeles area five months at the time of the birth of her first child. Her husband was a corporal in the Army, stationed at a camp in northern California. He had been in the service nine months. Mrs. E. lived with her sister and her sister's family. She contributed about $40 a month to the household. Her allotment during her pregnancy was $85. She worked during the first three months of her pregnancy as a waitress, earning approximately $32 a week. Mrs. E. moved into her mother's household after the birth of the child and lived there about five months, then moved back into her sister's household. With the birth of her child, her allotment was increased to $127.50. Her husband is now stationed in Korea and "I think he is a sergeant." Mrs. E. worked for two months after the birth of the child, earning approximately $55 a week. The contribution to the sister's household has remained the same.

Medical Care: Mrs. E. used the services of an Army infirmary for prenatal, postpartum and pediatric care. She delivered at a county hospital. Prenatal care began in the fourth month. Mrs. E. went to the infirmary once a month, by public transportation. She said it took approximately one hour to get there. She was hospitalized for five days, in a ward bed. She was seen at the infirmary for a postpartum examination at six weeks. The child has been taken to the infirmary approximately once a month since its birth.

Finances: Medical care at the infirmary was free. Mrs. E. has not received a bill for hospitalization.[5]

Attitude and Reasons for Choice: Mrs. E. indicated that "I could not afford private care," and that was why she chose the military facility for her prenatal care. She said, "I liked my care and only wish there had been a (military) hospital closer that I could have gone to." In addition to her prenatal care at the Army infirmary, it was necessary for her to go to a Navy hospital twice during her pregnancy, for "extra care and blood transfusion." Regarding her choice of the hospital, she said, "It was the only place I could afford to go. Private hospitals are too expensive and the military hospital was much too far. I could have never made it there on time." Her general attitude about the total maternity situation was, "It was wonderful to get everything free."

Case 6.—Background: Mrs. F., aged 24, has lived in Los Angeles all her life. Her husband, aged 23, is a private in the Army. He had been in the service approximately three months at the time of delivery. Mrs. F. received an allotment of $85. She worked until her seventh month of pregnancy as a waitress and earned $35 per week. She lived in her own apartment in a low-cost hotel during her pregnancy; her mother lived in the same hotel but they did not share quarters. Mrs. F.'s allotment was cut off at the time of the birth of her child, because her husband was AWOL. He is now waiting court martial at an Army camp. She is living on general relief, receiving $75 a month from the county. She has not worked since the birth of the child.

Medical Care: Mrs. F. used the services of a city public health department prenatal clinic. Her first visit to the clinic was during the fifth month. She went approximately every two weeks. The clinic was close enough for her to walk. Hospitalization for six days at the time of delivery was at a county hospital, in a ward. There have been no postpartum examinations since discharge from the hospital. The child has had pediatric care at a public health department clinic once a month since its birth. It had bronchitis shortly after birth and was hospitalized three days at the same county hospital.

Finances: There were no charges for prenatal, delivery, postpartum, or pediatric care. Mrs. F. has not been billed for hospitalization.

Attitudes and Reasons for Choice: Mrs. F. indicated she "could not afford a private doctor and the military clinic was too far." She said, "I would have preferred to have had my own doctor if I could have afforded it." She selected the county hospital for delivery and hospitalization "for the same reason." She indicated she was satisfied with the care she received.

---

[5] Patients in labor are eligible for admission to the county hospitals either as medically indigent residents of the county or because they are medical emergencies. Those who are dependent on a service allotment and who are or whose husbands are residents of Los Angeles County are not currently billed. They may at a later time, if an increase in their assets warrants, receive bills for the cost of care. The others are billed soon after discharge. Under state law and county ordinance, the cost of all medical care given is reimbursable and the county may attempt to recover the cost. Persons who appear to have no ability to pay are not pressed for payment.

THE LEISURE CORNER

THE FLOWERING HOBBY

A well-chosen hobby growing naturally out of innate desires, needs, and abilities makes a joyful contribution to the art of living when things go well in the practice of medicine and at the same time provides a sphere of activity to which it is possible to turn for solace when the problems of a busy medical life enlarge. High on the list of activities that can be pursued as a hobby is the ancient and enjoyable art of gardening. Raising flowers appeals to several senses and is full of rewards and surprises, for, besides the fact that it can be shared with others and thereby doubly enjoyed, its study and cultivation may also be carried as far and wide and made as specialized as the interested hobbyist wishes. Actually, horticulturists are ideal hobbyists for riding their hobby horses along garden paths and through the bypaths of suburban and metropolitan back yards, pausing to sniff graciously at the humble flower pot. To enter this kind of world, a love of flowers and plants and a bit of earth are the only equipment necessary to start the busy physician off on an interest that can lead to such highly specialized activities as the cultivation of prize-winning flowers.

Some years ago Charles Dudley Warner, the writer, expressed the belief that sooner or later an inborn love for the soil eventually makes itself known to every human being. "Mud pies," he asserted, "gratify one of our first and best instincts. Therefore, for those who ask, 'Who should attempt growing flowers?' the answer is 'Anyone who likes them well enough to take care of them.' " Since many flowers will thrive almost under any conditions if given reasonable attention, raising flowers is a pursuit suitable for physicians who reside in suburbs and rural communities and for city dwellers who are landless but not potless, or who, at best, are owners of a tiny back yard. Today more and more miniature gardens sprout in metropolitan environs; flowers need be neither confined to back yards and roofs nor limited to the restrictions imposed by indoor gardens or window boxes. Literally, a green fairyland can be the lot of the urban dweller who, by watching flowers and plants unfold their leaves and develop their blossoms, may indulge in flights of the imagination that will convey him above imaginary fields and mountainsides.

Flowers are mostly grown in gardens where, appropriately enough, they either mingle with other flowers or occupy an individual corner all by themselves. It is in home gardens that much experimental work on the propagation and growth of flowers has been carried on, and it is in precisely this milieu that the flowering hobbyist notices their virtues and their flaws. Here, the terminology of flower culture will carry the physician back to the day when he studied biology as a medical student—genes and chromosomes, pollen, fungi, viruses, and molds. There are vectors to be dealt with, and the process of hybridizing, and the breeding out of undesired traits in flowers while retaining more desirable characteristics.

Take the case of the African violet (Saintpaulia), a favorite American house plant, which grows well and blooms almost endlessly under conditions imposed by the average house dwelling, but which will not flourish so readily as to permit the disinterested person to neglect it or to lose interest in it. More than a half century ago the African violet was discovered in the hilly regions of eastern tropical Africa. From the day of its discovery, it took the horticultural world by storm, so that when in the autumn of 1946 the first African violet show was sponsored in Atlanta, Ga., the ensuing thousands of visiting violet fans required the attention of police to maintain traffic and order. Today, few persons dispute the possibilities of the African violet as a hobby plant for collectors, and at least 175 varieties appear by name in lists gathered throughout the United States.

While many plants are grown for their foliage, this is not the case of the African violet; since its native habitat is in shady nooks and in wooded places, it does not require a flood of sunshine. Indeed, too much sunshine affects foliage adversely, turning it yellow, burning the margin of leaves, or causing malformation of leaf and flower. In general, it flowers well in any light situation where brightness is somewhat diffused. The stronger the light the deeper the color tones and the greater the tendency to flower. The most satisfactory circumstance surrounding the African violet is its tolerance to the usual household heat and its ability to thrive in an atmosphere up to 75 F. A temperature less than 60 F impedes both growth and flowering. Many hobbyists have found that African violets bloom and thrive more freely if each plant is set on a pebble-filled saucer with some water in it as a ready means of humidifying the surrounding air.

African violets are easily propagated, and they multiply readily by means of division or through leaf propagation; moreover, they can be raised from seed, and from a single seed pod it is possible to obtain as many different varieties as there are seeds. Not so long ago there was but one type of Africa violet extant, a species known to the initiated as Saintpaulia ionanatha. Now there are scores. Definite strains and varieties are being grown, with purples, pinks, and whites abounding.

Diseases of the Retina. A. E. Maumenee.—p. 553.

Oxygen Supply in Ophthalmic Diseases.—The author studied the behavior of visual functions under modified oxygen supply in several ophthalmic diseases. A reduced oxygen supply to the visual apparatus was obtained by producing a general, more or less severe, anoxia by having the patient breathe an oxygen-poor mixture or by placing him in a depression chamber reproducing the conditions met in the normal atmosphere at between 13,000 and 26,000 ft. (3,900 and 7,800 m.). A reduction of the oxygen supply to only the retina and the optic nerve was obtained by exerting on the eyeball a graded amount of compression with a dynamometer, proportional to the arterial pressure of the retina. With such a technique, which produces only moderate changes of the visual functions in normal subjects, some visual deficiencies may be discovered, as follows: enlargement of the blind spot in early glaucoma; appearance of a central scotoma and pronounced decrease of visual acuity; reduction in the limits of the visual fields in certain neuroretinal diseases; occurrence of ignored hemianopsia in disorders of the intracranial optic pathways; severe impairment of seemingly normal muscle balance; impairment of the audiometric response, which appears to be typical for certain ocular diseases such as glaucoma; and an abnormal decrease of the flicker fusion frequency. Since the compression of the eyeball reduces the oxygen supply locally, while general anoxia involves the function of whole visual pathways, a difference in results of the two procedures sometimes permits localization of the lesion. The anoxia test is an additional diagnostic and prognostic procedure in the field of ocular diseases. Results of the author's study proved that the action of anoxia on the visual function is both peripheral and central. Additional studies were made by increasing the oxygen supply to the eye, chiefly through inhalation of pure oxygen at atmospheric pressure. This produced a reduction, or even disappearance, of scotomatous areas of the visual field, as well as improvement in the impaired visual functions in many ocular disorders. Areas that had not completely lost their function were revealed. The behavior of some visual functions under modified oxygen supply in several ophthalmic diseases represents a new procedure that may be of value in ophthalmology.

Myocarditis in Poliomyelitis.—The presence of acute myocarditis in patients dying of poliomyelitis has suggested that cardiac failure may be a principal or a contributing cause of death. The report is based on 47 fatal cases in which autopsies were done from 1942 to 1951, inclusive. Typical spinal and bulbar lesions of acute anterior poliomyelitis were present in all. Myocardial sections were fixed in Zenker's or alcohol-formaldehyde solutions, embedded in paraffin, and stained with hematoxylin and eosin. Acute myocarditis was found in 26 of the patients. During the epidemic of 1949, the incidence of myocarditis was much greater than in any other year (100%), and it was also severer. This corroborates evidence collected by other authors that during certain epidemics there are viscerotropic strains of the virus which may injure the myocardium. The occurrence of acute myocarditis could not be correlated with sex or age of the patient or with the occurrence of cardiac dilatation or hypertrophy. The significance of myocarditis in poliomyelitis is not fully understood. In many of the sections examined in this study, as well as in those reported in the literature, the inflammation is minimal and focal in distribution, and this fact raises a question of its functional significance. The myocarditis may be of only incidental importance, and the mechanism of its development remains unknown.

Carcinoma of Breast During Pregnancy.—A questionnaire concerning carcinoma of the breast during pregnancy was submitted to 55 physicians who had either published papers on the subject or who were considered to be especially interested in it. The questionnaire covered the following points: the number of cases of carcinoma of the breast developing during pregnancy, number of five year cures obtained, operability

---

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

rate, whether pregnancy following a previous radical mastectomy increases the chances of development of carcinoma in the remaining breast, advisability of interruption of pregnancy in a patient in whom carcinoma of the breast develops in the first, second, or third trimester of pregnancy, and advisability of tubal sterilization or ligation following radical mastectomy in the premenopausal woman to prevent further pregnancies. Replies to the questionnaire were received from 47 physicians, but not all of them commented on all five questions. The survey indicates that, although results of treatment of carcinoma of the breast in pregnancy are disappointing and the prognosis is poor, the prognosis need not be invariably hopeless. Occasional five year cures have been reported. None of the respondents considered pregnancy itself an absolute contraindication to surgery. Termination of pregnancy seems to be indicated, particularly if the cancer is discovered during the first half of gestation. There is general agreement that subsequent pregnancies should be avoided by women who have had mammary carcinoma, but most physicians thought that conventional contraceptive measures would be adequate. A few considered surgical castration advisable. Whether pregnancy may increase the chances of carcinoma developing in the remaining breast remains an unsettled point. Most of those who replied thought that it would not. Any hope for improvement of the prognosis lies in recognition of the growth at a stage when it is still operable. Obstetricians should examine the breasts of their patients at frequent intervals. Instruction of patients concerning technique of examination of their own breasts may be of considerable value.

Cancer Detection.—This paper reports the results of 2,111 initial examinations of adults at the Kips Bay-Yorkville Cancer Detection Center, a pilot project of the department of public health and preventive medicine of Cornell Medical College and the New York City Department of Health. The study was undertaken to evaluate cancer detection in adult health services. Twenty-seven (1.3%) of the examinees were found to have cancer, even though the group had been prescreened to exclude persons with symptoms suggesting malignancy. More than half of the patients found to have cancer had no symptoms. These instances of asymptomatic cancer (the true cancer detections) constituted 0.8% of all persons examined. Precancerous neoplasms and other lesions requiring care as a precaution against cancer contributed 14.3 diagnoses on the average for each 100 persons examined. Polyps of the colon and rectum constituted the largest component of the precancerous group. Routine proctosigmoidoscopy revealed neoplastic lesions (mostly polyps) in 5.0% of males and 3.7% of females on first examination. An additional 2.7% showed such lesions on reexamination after approximately one year. Pathological conditions not related to cancer were almost nine times as numerous as cancer and precancerous lesions. Such diagnoses averaged 131 per 100 examinees, or more than one for each person examined. The authors feel that the following are among the most significant contributions of the cancer detection service: 1. The diagnosis of a small number of cases of asymptomatic cancer. 2. The impetus given to the study and the treatment of conditions assumed to be precancerous. 3. The detection in presumably healthy adults of a large number of pathological conditions unrelated to cancer. 4. The initiation of corrective measures and early treatment by referral.

Apical and Aortic Systolic Heart Murmurs.—Results of a follow-up study of 1,212 patients with cardiovascular disease with slight or moderate systolic murmurs were compared with those of 187 patients with loud or very loud systolic murmurs and with those of 200 patients who had no murmurs. None of the patients had diastolic murmurs, and the systolic murmurs were loudest at the cardiac apex or aortic valve. There were slightly more patients with slight or moderate murmurs than patients without murmurs; the ratio of persons with slight or moderate murmurs to patients with loud and very loud murmurs was 6½:1. The ratio of men to women (3:2) and the age incidence (most of the patients were over 50) were the same for all three groups. Patients with coronary or hypertensive heart disease, or both, outnumbered those with other types of heart disease in all three groups. There seemed to be a great difference in the prevalence of rheumatic heart disease, however, which was observed in 27% of the patients with loud murmurs, in only 3% of those with lesser murmurs, and in none of those without murmurs. There were patients with other or unidentified types of heart disease. The systolic murmur was maximal over the aortic valve rather than the apex in about one-fifth of the patients with murmurs, but in 26% of those with lesser murmurs there seemed to be little difference between the aortic and apical intensities. Those with the loudest murmurs had shorter lives than those with lesser or no murmurs, but occasionally patients (8%) with loud and very loud murmurs were still alive more than 15 years after the murmurs were discovered. The relation of the intensity of the murmurs to mortality was qualified by three other important findings: The mortality among men was greater than that among women in all the groups. Pre-existing coronary or hypertensive heart disease was much more serious than rheumatic heart disease. Younger age was probably a factor in some of the rheumatic cases. No evidence was revealed that aortic systolic murmurs without diastolic murmurs have any more unfavorable prognosis per se than apical systolic murmurs. One of the most impressive findings was that moderate to great heart enlargement predisposed to early death in all of the patients. This was a more important factor in all the three groups of patients than any other, including loudness of the murmur itself. Many murmurs reveal the presence of strain-producing valvular defects, but such defects vary greatly in importance, as do patients in their ability to resist such strain.

Association of Polycystic Kidneys with Intracranial Aneurysms.—Congenital intracranial aneurysm and polycystic renal disease were associated in 32 cases collected from the literature. This incidence suggests that more than coincidence is involved in this relationship. The presence of these two lesions in three additional patients is reported. In the first patient, aged 33, death was due primarily to slow bleeding from an intracranial aneurysm; the presence of polycystic kidneys was revealed by necropsy. In the second patient, aged 62, death was due to uremia from failure of the polycystic kidneys, and the presence of a symptomless intracranial aneurysm was disclosed by careful examination of the cerebral arteries. In the third patient, aged 52, illness and death were caused by a widespread bronchogenic carcinoma. Two minute unruptured intracranial aneurysms and polycystic kidneys were accidental postmortem discoveries. Other anomalies such as coarctation of the aorta, biliary cysts, and cysts of the pancreas that have been observed in association with either intracranial aneurysms or congenital polycystic kidneys are discussed. Polycystic disease of the kidneys may represent one phase of a disseminated congenital disorder somewhat analogous to tuberous sclerosis, neurofibromatosis of Von Recklinghausen, or Lindau-Von Hippel disease.

Identification of Pinta in Mexico.—Most of the estimated 250,000 victims of pinta in Mexico live in the valley of the Balsas River; the Tepalcatepec River is its most important tributary. The Center of Epidemiological Studies is making a study of pinta in the Tepalcatepec Basin, taking into account family relationships, domiciliary conditions, nutritional status, employment, exposure to and acquisition of other endemic diseases, and other factors with the hope of learning more of the nature of the disease, its transmission, and epidemiological control. Pinta is principally a disease of the skin that generally causes no disability or serious physical handicap. The victims of the disease move freely only in the geographic regions where the disease is endemic, because they are considered socially undesirable in pinta-free communities owing to the belief that the disease is contagious. Pinta, therefore, takes on socioeconomic importance. The main effects of the disease are disturbances in the normal pigmentation of the skin, often of unsightly character. In this first of the four reports a study is reported on 121 of 256 inhabitants of Capirio, a village on the Tepalcatepec River. The study consisted of examination of the exposed surfaces of the body (head and neck, chest in whole or parts, arms, thighs, and legs), serologic tests for syphilis, and in some cases the Treponema pallidum immobilization test and dark-field examinations. In all patients with pinta the Treponema pallidum immobilization tests were positive. In two patients the standard serologic tests and the Treponema pallidum immobilization differed; no pinta was observed in either patient. To check the accuracy of self-diagnosis of pinta or of that made by an older member of the family, a comparison was made between the self-diagnosis and the diagnosis arrived at by the examining dermatologist. Four errors in self-diagnosis were found in 64 patients. With this degree of accuracy, the following incidence of pinta was found in the families of the Capirio community. Of the 54 families with 256 persons, there were 39 families in which living members had a history of pinta. In 12 families one-half or less of the members had the disease, and in 27 families more than one-half of the family were affected, all members being affected in 11 of these 27 families.

Pinta in Mexico: Mass Survey Considerations.—In this second of the four reports results of a clinical and serologic study of pinta are presented. Exposed surfaces of the skin were examined and serologic tests done for syphilis in 238 persons, of whom 52 were found to have pinta. Examination of the exposed surfaces of the body proved efficient for field identification of the disease. Clinical diagnoses made by this method were confirmed by serologic studies with very few exceptions. Serologic examinations are considered not necessary or practical as a case-finding device in mass surveys for pinta. There is no way of making the differential diagnosis serologically between syphilis and pinta. Since it is extremely unlikely that syphilis is not extant to some degree in these populations, the reactions found in the untreated group are probably syphilitic, biologic false-positive reactions, or results of treatment in persons who denied it but nevertheless had been adequately treated for pinta. In the towns studied, medical care was given by practical nurses, who treated pinta patients with penicillin and/or arsenicals under medical supervision. In the two communities in which many of the patients had been treated previously, pinta was found to be disappearing, as evidenced by the relatively few cases of the disease found among children. The control of pinta is believed possible by adequate treatment of clinical cases, vigilance for, and prompt treatment of newly infected patients appearing or arriving in the treated areas, and proper re-treatment of recurrent disease.

Aureomycin in Actinomycosis.—Seven of 10 patients with actinomycosis observed at the John Gaston Hospital and the University of Tennessee College of Medicine were treated with aureomycin. Six patients had cervicofacial actinomycosis and one had hepatic actinomycosis and a hepatic abscess caused by Actinomyces bovis and Bacteroides funduliformis. Aureomycin in doses of 750 mg. administered orally every six hours for 10 days and thereafter in doses of 500 mg. every six hours for 18 days was effective in cervicofacial actinomycosis. In four patients with localized cervicofacial actinomycosis the follow-up periods were 36, 33, 32, and 25 months respectively; in three of these actinomycosis followed extraction of teeth. There were no recurrences of the disease in these patients. The patient with hepatic actinomycosis who had been critically ill was entirely asymptomatic 30 months after treatment with aureomycin; he was working regularly and had maintained his normal weight for more than two years. Results of serial hematological examinations remained normal. Prolonged treatment with aureomycin by the intravenous route may be required in this severe form of the disease. Observation for five years following treatment may be necessary to establish definitely the cure of systemic or visceral actinomycosis. The authors consider aureomycin an effective agent in the treatment of localized and disseminated actinomycosis. Aureomycin exerts a definite inhibitory effect on Actinomyces bovis in vitro.

Pure Mitral Insufficiency of Rheumatic Origin.—At necropsy after death from heart disease in 44 cases, 5 cases of pure and isolated incompetence of the mitral valve were found without deformity of any other valve, pericarditis, hypertension, coronary artery disease, syphilis, or any other but rheumatic cardiac involvement except for bacterial endocarditis in one patient. In four of the five patients death resulted from mitral regurgitation causing intractable fatal congestive heart failure. In none was there any clinical or pathological evidence of an active rheumatic process. Modern textbooks and the current literature create the impression that in adults fatalities from heart failure occur only rarely during pure mitral insufficiency. The evidence presented here shows that death from this cause may occur in adults, even in advanced middle life, more frequently than is currently believed. All four patients had a loud, harsh systolic murmur, heard over the entire precordium, with maximal intensity over the apex, and radiation to the axilla, lung base, and along the spine as far down as the sacrum. The authors believe that even in the absence of a history of rheumatic fever, a murmur of this type, with or without an accompanying thrill, in combination with left atrial and ventricular enlargement, constitutes in adults a sign pathognomonic of organic mitral regurgitation. Sclerosis of the pulmonary vascular system was not observed in the authors' patients with pure mitral insufficiency.

Diagnosis and Antibiotic Therapy of Amebiasis.—Diagnosis of amebiasis of the colon or liver was made in 50 patients by sigmoidoscopy, by examination of mucus obtained by mucosal swabs, or by examination of feces. Sigmoidoscopy, with immediate examination of mucus, is the most practical method of diagnosis. It is easier and more productive than frequently repeated examinations of purged stools. Single stool specimens, or repeated specimens not obtained by purging, resulted in a low rate of successful diagnosis. Negative results shown by sigmoidoscopy and examination of the mucosal aspirate are essential criteria of cure. The use of less rigid criteria has resulted in the overenthusiastic and contradictory reports as to the efficacy of antibiotic drugs. Of 40 patients with intestinal amebiasis 27 were treated with oxytetracycline (Terramycin) and 13 with aureomycin; amebas were still found in 17 cases after one course of oxytetracycline and in 13 after a second course. Specimens from 4 of these 13 patients became negative after a seven day course of oxytetracycline and emetine. Five of the 13 patients treated with aureomycin were therapeutic failures. The use of antibiotics for the intestinal form of the disease was not only disappointing in failure to obtain cure but also in the development of serious untoward effects on prolonged treatment. The results with antibiotics were no better than those previously reported with potentially less toxic drugs. Results with chloroquine and emetine in the hepatic form of the disease were variable. Reinfection from uncontrolled intestinal amebiasis may give a false picture of the efficacy of these drugs. Eight illustrative cases are described, placing emphasis on the unusual clinical pictures that may occur and on the need for awareness of the prevalence of amebiasis in both civilian and military medicine.

Autopsy Study of Latent Prostatic Cancer.—The authors studied two series of autopsies in patients 40 or more years of age. In one series, the incidence of latent prostatic cancer was 14.8% in 81 cases; in the other series, it was 16.6% in 173 cases. The morphology of the small latent cancers appeared similar to that of clinically manifest prostatic carcinoma, although there was less infiltration. Early carcinoma originated from the peripheral prostatic tubules in 87.5% of cases; it was not infrequently multicentric. A statistically significant relationship could be demonstrated between prostatic carcinoma and benign hyperplasia; the nature of this association remains obscure. No statistically significant relationship could be demonstrated between prostatic carcinoma and prostatitis, prostatic calculi, or primary malignant disease in other body regions.

Peripheral and Multiple Bronchial Adenomas.—Bronchial adenomas may be termed "carcinoid" or "cylindroid" according to their resemblance to such neoplasms in other organs without implying any definite histogenesis. Although some of these tumors are locally invasive and capable of metastasizing, their development differs sharply from that of the much more rapidly progressive, destructive, and disseminating bronchogenic carcinoma. Bronchial adenomas occur predominantly in the main stem or lobar bronchi. This report deals with four cases of peripheral bronchial adenoma. In two patients of this series the lesions were multiple, and the evidence indicated that metastasis had not occurred. One of these offered a unique opportunity to study the histogenesis of peripheral bronchial adenoma. Both of these patients underwent pulmonary resection, and in the other two the tumors were found at necropsy. Observations on these four cases demonstrate that tumors with the structure of bronchial adenoma can originate in small bronchi or bronchioles and possibly even in respiratory bronchioles; that such lesions may be multiple is exemplified in two. The absence of lymphatic or lymph node involvement, together with other evidence such as the diversity in structure of adenomas of different sizes, suggests that these tumors were multicentric in origin rather than the result of intrapulmonary metastasis. In such a peripheral position there is evidence, based on the study of serial sections from one lesion, that bronchial adenomas can arise from the epithelial lining. This does not deny their possible origin from mucous glands or their ducts when they arise in their usual position within proximal bronchi. These smallest lesions are not encapsulated, and their component cells tend to have scanty cytoplasm and an acinar arrangement with a tendency to line preexisting respiratory passages. In one patient it was possible to trace numerous transitional forms from such lesions to larger tumors of the usual structure. More data are needed concerning the age incidence of these peripheral adenomas that, in the experience of these authors, appear to occur in an older age group than the more central lesions.

Remissions in Leukemia After Infections.—Sporadically during the last 75 years there have been reports suggesting that severe infections may sometimes favorably modify the course of far-advanced neoplastic disease. More recently, attention has again been directed to the association of acute infections with clinical remissions of leukemia in children. Bierman and associates present case histories of 11 children in whom infections developed in the course of lymphatic leukemia. Marked clinical and hematological remission of the leukemia was seen in two children with hemolytic Staphylococcus septicemia, in one child with varicella, and in one child who was infected with the feline panleukopenia virus. Similar but less complete effects were observed in six other children. The sequence of events in these remissions is as follows: A child with acute lymphatic leukemia, with a high or a low leukocyte count and with or without a marked granulopenia, contracts an infection that is followed by fever, drop in the peripheral leukocyte count, and occasionally by a hypoplastic phase in the bone marrow. If the patient survives this phase, the hemogram returns toward normal and a temporary clinical remission may occur. In all cases the leukemic process returned, and no evidence is available from the present data that such remissions were associated with a significant prolongation of life. The authors feel that the rapid and almost complete return toward normal hematological and clinical appearance in some children with fulminant leukemia following acute infections is a strong indication that some major features of leukemia are reversible.

Noise in Industry.—Managers of factories are beginning to realize that compensation claims for occupational loss of hearing may become more numerous. In one state compensation claims for occupational loss of hearing amounting to more than 5 million dollars have been filed against one company alone. In Wisconsin some 40-odd cases originating in two drop forge plants were filed. It is estimated that there are from 25,000 to 100,000 potential cases in Wisconsin that are being held up pending judgment of the State Supreme Court in a test case in which the Industrial Commission held that wage loss is not necessary, because loss of hearing is a schedule injury in that state. A bill has been introduced in the Wisconsin legislature asking that hearing loss cases be put on a wage-loss basis. Under this bill, as introduced, compensation would not be payable for occupational hearing loss unless there was a wage loss, and the maximal benefits would be set at $3,500. The author calls attention to some of the complexities, such as how to distinguish between occupational and nonoccupational loss of hearing. A standard technique must be established for measurements of hearing impairment. Related problems must be studied, such as the effect of vibration upon hearing and the development of tests that might predict which persons are unusually susceptible to hearing impairment. Recognizing that unless there is close cooperation and coordination of research, much time and money will be dissipated in the study of the problem of noise in industry, representatives of a number of interested groups have asked the Industrial Hygiene Foundation to participate as the coordinating agency in a program designed to provide practical information that can be used for developing control measures and for establishing regulations that will be equitable and practical. The important objectives of such a study are to find and define basic criteria for the appraisal of the effects of noise on hearing; to establish a correlation between loss of hearing and exposures to noise intensity levels in the various frequency bands; to evolve control procedures to reduce noise to acceptable levels; and to develop evidence that may lead to establishment of equitable regulations for coping with the legal aspects of the problem.

Disability Due to Inhalation of Grain Dust.—Respiratory disability is reported in 11 workers from grain elevators and feed mills in the Buffalo, N. Y., area. Each worker had been referred to an allergist because of symptoms suggestive of asthma. There was progressive dyspnea at rest and on exertion, cough, and frequently "wheezing." Each of these men had worked in the environment of crude grain dust for 10 years or more before well-pronounced symptoms appeared. All attributed their symptoms to the inhaled dust. The onset of symptoms was gradual. The symptoms, especially the dyspnea, showed a progressive increase until they became disabling. Examination showed evidence of chronic bronchitis, recurrent bronchial obstruction, and clinically apparent emphysema in 8 of the 11 patients. Nine of the 11 were tested with extracts of crude grain dust. Five of the patients were considered sensitive to grain dust and four were not. Four of the 11 patients died while under observation, and necropsies were performed in 3 of these. Pathological findings consisted of pronounced pulmonary fibrosis and emphysema, with cor pulmonale in two. There was no evidence of silicosis or fungus disease. The authors believe that workers handling crude grain may become allergically sensitive to crude grain dust or to some of its allergenic components, and that this sensitivity can result in disabling respiratory disease when the exposure is continued over a long period of time. Allergic sensitivity to crude grain dust is not the only causative factor in the production of the grain handler's disease. Crude grain dust inhaled over a long period of time can induce disabling respiratory symptoms and pulmonary changes in the absence of allergic sensitivity. The authors suggest that experimental work on lower animals should be carried out to determine whether exposure over long periods to an atmosphere laden with grain dust can induce chronic pulmonary changes or allergic sensitivity or both.

Allergy in Identical Twins.—In only 7 of 59 pairs of monozygotic, identical twins studied by Bowen were allergies present in both twins. The youngest pair was 8 weeks old, and the oldest 56 years; most were between 6 and 15 years of age. In the seven pairs of twins in which both had allergies three pairs had juvenile eczema, and in two of these asthmatic symptoms occurred later. Two other pairs had severe pollinosis of the perennial and ragweed types. Two others had classical bronchial asthma. In some of the remaining 52 pairs some of the twins had bronchial asthma with coexisting nasal blockage, but in this group only one of each pair was affected to such a degree that medical help was sought. The fact that in only seven pairs was there true allergy of similar pattern in both twins contradicts the concept that allergic manifestations are the result of placental transference. Many of these children were as young as 2 months when they first experienced their symptoms, which poses an interesting problem for the proponents of maternal rejection as an etiological factor. Brain wave studies were made in three pairs of twins; findings tended to be similar irrespective of the presence or absence of active allergy. The results of this survey also challenge the concept that maternal dietary restrictions during pregnancy will make allergy less likely to appear in the newborn.

Effect of Vagotomy on Gastric Evacuation of High-Fat Meals.—The presence of fat within the upper intestine has been shown to depress the secretory and motor activity of the stomach. The role of the vagus nerves and the part played by reflex mechanisms in controlling gastric evacuation after fatty meals have been studied in animals, and the conclusions reached were that reflexes mediated over the parasympathetic nerves did not influence the behavior of the stomach significantly. New evidence concerning these problems obtained by simple techniques on human subjects are presented. It was found that the introduction of a high-fat meal into the normal stomach or one with a gastroenterostomy is followed by prolonged delay in gastric emptying. This effect is abolished by partial gastrectomy or by vagotomy in the presence of a gastroenterostomy. This seems to indicate that gastric was 14.8% in 81 cases; in the other series, it was 16.6% in 173 cases. The morphology of the small latent cancers appeared similar to that of clinically manifest prostatic carcinoma, although there was less infiltration. Early carcinoma originated from the peripheral prostatic tubules in 87.5% of cases; it was not infrequently multicentric. A statistically significant relationship could be demonstrated between prostatic carcinoma and benign hyperplasia; the nature of this association remains obscure. No statistically significant relationship could be demonstrated between prostatic carcinoma and prostatitis, prostatic calculi, or primary malignant disease in other body regions.

Peripheral and Multiple Bronchial Adenomas.—Bronchial adenomas may be termed "carcinoid" or "cylindroid" according to their resemblance to such neoplasms in other organs without implying any definite histogenesis. Although some of these tumors are locally invasive and capable of metastasizing, their development differs sharply from that of the much more rapidly progressive, destructive, and disseminating bronchogenic carcinoma. Bronchial adenomas occur predominantly in the main stem or lobar bronchi. This report deals with four cases of peripheral bronchial adenoma. In two patients of this series the lesions were multiple, and the evidence indicated that metastasis had not occurred. One of these offered a unique opportunity to study the histogenesis of peripheral bronchial adenoma. Both of these patients underwent pulmonary resection, and in the other two the tumors were found at necropsy. Observations on these four cases demonstrate that tumors with the structure of bronchial adenoma can originate in small bronchi or bronchioles and possibly even in respiratory bronchioles; that such lesions may be multiple is exemplified in two. The absence of lymphatic or lymph node involvement, together with other evidence such as the diversity in structure of adenomas of different sizes, suggests that these tumors were multicentric in origin rather than the result of intrapulmonary metastasis. In such a peripheral position there is evidence, based on the study of serial sections from one lesion, that bronchial adenomas can arise from the epithelial lining. This does not deny their possible origin from mucous glands or their ducts when they arise in their usual position within proximal bronchi. These smallest lesions are not encapsulated, and their component cells tend to have scanty cytoplasm and an acinar arrangement with a tendency to line preexisting respiratory passages. In one patient it was possible to trace numerous transitional forms from such lesions to larger tumors of the usual structure. More data are needed concerning the age incidence of these peripheral adenomas that, in the experience of these authors, appear to occur in an older age group than the more central lesions.

Remissions in Leukemia After Infections.—Sporadically during the last 75 years there have been reports suggesting that severe infections may sometimes favorably modify the course of far-advanced neoplastic disease. More recently, attention has again been directed to the association of acute infections with clinical remissions of leukemia in children. Bierman and associates present case histories of 11 children in whom infections developed in the course of lymphatic leukemia. Marked clinical and hematological remission of the leukemia was seen in two children with hemolytic Staphylococcus septicemia, in one child with varicella, and in one child who was infected with the feline panleukopenia virus. Similar but less complete effects were observed in six other children. The sequence of events in these remissions is as follows: A child with acute lymphatic leukemia, with a high or a low leukocyte count and with or without a marked granulopenia, contracts an infection that is followed by fever, drop in the peripheral leukocyte count, and occasionally by a hypoplastic phase in the bone marrow. If the patient survives this phase, the hemogram returns toward normal and a temporary clinical remission may occur. In all cases the leukemic process returned, and no evidence is available from the present data that such remissions were associated with a significant prolongation of life. The authors feel that the rapid and almost complete return toward normal hematological and clinical appearance in some children with fulminant leukemia following acute infections is a strong indication that some major features of leukemia are reversible.

Noise in Industry.—Managers of factories are beginning to realize that compensation claims for occupational loss of hearing may become more numerous. In one state compensation claims for occupational loss of hearing amounting to more than 5 million dollars have been filed against one company alone. In Wisconsin some 40-odd cases originating in two drop forge plants were filed. It is estimated that there are from 25,000 to 100,000 potential cases in Wisconsin that are being held up pending judgment of the State Supreme Court in a test case in which the Industrial Commission held that wage loss is not necessary, because loss of hearing is a schedule injury in that state. A bill has been introduced in the Wisconsin legislature asking that hearing loss cases be put on a wage-loss basis. Under this bill, as introduced, compensation would not be payable for occupational hearing loss unless there was a wage loss, and the maximal benefits would be set at $3,500. The author calls attention to some of the complexities, such as how to distinguish between occupational and nonoccupational loss of hearing. A standard technique must be established for measurements of hearing impairment. Related problems must be studied, such as the effect of vibration upon hearing and the development of tests that might predict which persons are unusually susceptible to hearing impairment. Recognizing that unless there is close cooperation and coordination of research, much time and money will be dissipated in the study of the problem of noise in industry, representatives of a number of interested groups have asked the Industrial Hygiene Foundation to participate as the coordinating agency in a program designed to provide practical information that can be used for developing control measures and for establishing regulations that will be equitable and practical. The important objectives of such a study are to find and define basic criteria for the appraisal of the effects of noise on hearing; to establish a correlation between loss of hearing and exposures to noise intensity levels in the various frequency bands; to evolve control procedures to reduce noise to acceptable levels; and to develop evidence that may lead to establishment of equitable regulations for coping with the legal aspects of the problem.

Chordoma of Lumbar Vertebra.—Chordoma is a slow-growing malignant tumor that arises from elements of the primitive notochord. Over 300 cases of chordoma have been reported. The lesion most commonly arises in the sacrococcygeal region. Cranial chordomas are next in frequency. These usually arise in the sphenoid or the spheno-occipital region. Chordomas arising in the vertebral region are the least common, comprising less than 15% of the known cases. The vertebral lesions occur oftenest in the lumbar region. Observations on a new case of vertebral chordoma are presented. The patient, a 39-year-old man, was admitted to the bone tumor service in November, 1951, with the chief complaint of low back pain. The patient had sustained a back injury in an automobile accident in 1943, but after that he had no back symptoms until April, 1951, when he had an episode of dull continuous low back pain lasting 10 days and subsiding without treatment. In September, 1951, while he was bending, a severe pain developed in the midlumbar region, radiating into the right thigh and knee. The patient was admitted to his community hospital with a provisional diagnosis of herniated intervertebral disk. He was treated for 10 days by traction on the right lower extremity, followed by application of a plaster jacket. These measures relieved the back pain only slightly. Films of the lumbar portion of the spine revealed an irregular area of bone destruction involving the posterior two-thirds of the body of the third lumbar vertebra. An aspiration biopsy of this vertebra revealed only blood and calcified debris. On Nov. 14, 1951, the lumbar spine was explored surgically and a biopsy specimen obtained. At operation, a diffuse area of softening and bone destruction was encountered in the lamina of the third lumbar vertebra. The bone was replaced by a mass of soft, rather gelatinous material that was brick-red in color. On the basis of an immediately air-fixed smear of the specimen stained with hematoxylin and eosin a diagnosis of chordoma was made; the microscopic appearance was typical. Following operation, the patient was fitted with a spinal brace that allowed him to become ambulatory, and x-ray therapy was started. A tumor dose of 1,560 r was given in two weeks. The therapy was then continued on the million-volt machine. A total tumor dose of 3,940 r was delivered to the third lumbar vertebra in slightly less than one month. The patient was symptomatically improved within a month after completion of the radiation therapy. The patient has been followed regularly in the bone tumor clinic and has shown continued improvement. Roentgenographic examination of the spine in September, 1952, disclosed no activity of the disease.

Multiple Bone Lesions in Letterer-Siwe Disease.—Fisher reports a case of Letterer-Siwe disease that provided an opportunity to investigate the development and healing of the bone lesions and revealed what appears to be the causative organism. The patient presented roentgenographic evidence of multiple destructive and productive lesions of the long bones, skull, and ribs, associated with generalized lymphadenopathy, fever, rapid pulse, anemia, and slightly depressed leukocyte count. A progressive course brought the patient close to death in eight months. The patient, a 2-year-old boy, responded to antibiotic therapy. This is the fifth case of Letterer-Siwe disease in the past two years in which clinical cure was obtained by treatment with antibiotics. Over the course of a year, six surgical biopsies were done. The original biopsy specimen showed nonlipid histiocytosis compatible with Letterer-Siwe disease. The second specimen showed the development of a lipid histiocytosis. The blood and tissue cultures revealed paracolon bacilli of the Arizona group. The author feels that Letterer-Siwe disease should no longer be considered inevitably fatal. This case strongly supports the concept of an inflammatory basis for this group of diseases. The findings in serial biopsy specimens also support the concept that Letterer-Siwe disease and Hand-Schüller-Christian disease are the same disease in different histological phases. Multiple biopsies and blood cultures are indicated for identification of causative organisms in similar cases. Antibiotic treatment is indicated even in the absence of a bacterial culture. The antibiotics of choice are probably chloramphenicol and oxytetracycline (Terramycin). Penicillin seems to be the least effective antibiotic against organisms likely to cause the condition.

Pulmonary Air Cysts.—Harden discusses air cysts on the basis of observations on 16 patients at Bellevue and 10 at Freedman's Hospital. The patients were from 18 to 69 years old, and all but 6 were men. The most frequent signs and symptoms were pulmonary emphysema, respiratory difficulty, cyanosis, wheezing, dyspnea, cough, chest pain, hemoptysis, repeated respiratory infections, and pneumonia. Four groups of cases are differentiated, on the basis of the bronchial communication and the functional state of the remaining lung. In the group 1 patients, in whom large air cysts communicate with the bronchial tree, the maximum breathing capacity was normal or slightly reduced. The patients of group 2 had large cysts with poor or intermittent bronchial communication but the remaining lung was apparently normal. The total lung volume was greatly restricted in all cases of group 2. The spirogram showed expiratory obstruction and air trapping. Irregularity of the respiratory movements was also observed. Patients of group 3a had air cysts with poor or intermittent bronchial communication associated with chronic diffuse emphysema in the remaining lung. The maximum breathing capacity was severely restricted but improved with bronchodilator drugs. Patients of group 3b also have low oxygen and high carbon dioxide tension in the alveolar air, which is reflected in the unsaturation of arterial blood that may result in cyanosis. Efforts should be made to prevent respiratory infections in patients with pulmonary air cysts, but, when respiratory infection develops, it should be combatted with antibiotics and chemotherapy. The use of oxygen may benefit these patients, particularly when heart failure or pneumonia develops, but hazards connected with the use of oxygen should be kept in mind. If the symptoms are severe enough to interfere with the patient's ability to work or are otherwise unduly incapacitating, surgical treatment is indicated for group 1 patients. In group 2 patients, surgery is the treatment of choice when the condition of the patient permits it. The use of surgery in group 3a depends largely on the condition of the patient, that is, whether he would survive surgery, and also whether he would still have respiratory insufficiency. The patients in group 3b have ventilatory and alveolar respiratory insufficiency. Even if they survive the operation, the symptoms may be intensified and hence surgical treatment is not advisable in the majority of these patients. Surgical treatment is indicated primarily when the other lung is normal and in some cases when the emphysematous changes in the other lung are not complicated by alveolar respiratory insufficiency.

Benzotropine Sulfonate in Parkinsonism.—Since the atropine series has long been known to include the most efficacious antiparkinsonism drugs and since antihistaminic drugs offered some promise in therapy, an attempt was made to combine the two chemical groups. A preparation known by its experimental number MKO-2, or benzotropine sulfate, was used in 24 patients; in 10 the parkinsonism was due to arteriosclerosis and in 14 was postencephalitic. Tremor and rigidity were present in all 24 patients, but in 10 patients tremor predominated; in 7 patients tremor and rigidity were equally incapacitating. Oculogyric crises occurred in three patients. One patient was bedridden and six patients were ambulatory but could not engage in any useful activity; 14 patients were able to carry on minor activities, and 3 patients were able to continue their usual activities. Benzotropine sulfate was administered in tablets containing 0.5, 1.0, or 2.0 mg. The total dose per patient varied from 1.5 to 6.0 mg. per day. Six of the patients had received no antiparkinsonism therapy prior to the administration of benzotropine sulfate; 18 had previously received other medications. The patients were followed for from 3 to 12 months while receiving benzotropine sulfate. Although no patient could be classified as recovered while under treatment with benzotropine sulfate, 3 showed great improvement, 14 showed moderate to slight improvement, 9 showed moderate improvement, and 5 fair improvement. Seven failed to improve. In no patient was the parkinsonism made worse by benzotropine sulfate. The authors conclude that benzotropine sulfate is an effective agent in the treatment of parkinsonism, comparing favorably with previously tried medications and tending to be more effective in severer cases. There are fewer toxic effects with comparable doses than with other atropine drugs.

Effect of Cortisone Therapy on Incidence of Rheumatic Heart Disease.—An attempt was made to assess the effect of cortisone in rheumatic heart disease by comparing a group of 100 patients treated with cortisone and a group of 80 patients cared for under similar circumstances before cortisone was utilized. All of the children had active rheumatic fever, fulfilling the diagnostic criteria of Jones. Cortisone was given intramuscularly to 56 patients, the usual regimen being 200 mg. for two days and 100 to 150 mg. daily thereafter for 21 days. Ten patients received the hormone for 31 to 50 days. Cortisone was given orally to 32 patients in doses of 200 mg. for two days and 100 to 150 mg. daily for 28 days and to 6 patients for 40 to 84 days. Six patients received corticotropin intramuscularly in daily doses of from 40 to 60 mg. for 7 to 40 days. There was no significant difference in the incidence of heart disease in the group that received cortisone and the group that did not. During cortisone therapy the appearance of well-being and marked clinical improvement in some children with acute carditis is so striking that the similarity of the incidence of heart disease is surprising. The possibility that the mortality of acute rheumatic fever will be reduced by cortisone remains to be assessed.

Absolute Eosinophil Count in Diagnosis of Neoplasms.—Patients with pulmonary lesions and white blood cell counts of over 10,000 were selected for this study. Later only those with white blood cell counts of over 15,000 were studied. A total of 25 patients were investigated, and in addition 122 cases of carcinoma of the lung were reviewed to determine the incidence of leukocytosis. Of the 25 patients studied, 18 had a pulmonary neoplasm, 6 had lung abscess, and 1 had a lung cyst. Five of the 18 patients with carcinoma of the lung had roentgenologic pictures resembling lung abscess.

These five patients with necrotic tumors were found to have white blood cell counts above 30,000 and eosinophil counts above 500. These findings were compared with similar observations in six cases of lung abscess in which there was no eosinophilia associated with the leukocytosis. Records of 122 patients with carcinoma of the lung revealed that 3.3% had white blood cell counts over 30,000. In cases in which differentiation of a malignant from an infectious process is difficult, the eosinophil count may be a valuable test. This investigation suggests that the toxic effects of a necrotic neoplasm produce a leukocytosis involving all of the white blood cells. The absolute eosinophil count could be used in the differentiation of carcinoma from infection in these cases.

Irradiation Treatment of Malignant Disease in Pregnancy.—Two pregnant women with Hodgkin's disease and three pregnant women with cancer of the breast, lymphosarcoma and leukemia, respectively, were given x-ray irradiation treatment. With the exception of the women with leukemia, the patients were delivered of normal babies. The spleen area in the leukemic patient was irradiated, suggesting the advisability of terminating the pregnancy. Twin fetuses removed by hysterotomy showed no ill effects of irradiation. The patient died shortly after the operation. The patient with cancer of the breast had an apparent arrest of the malignant process for a time after the delivery. Her condition gradually deteriorated and she died. The patient with lymphosarcoma, whose lesions remained quiescent during pregnancy, manifested symptoms with enlargement of the lymph nodes in the neck after the delivery of her baby. X-ray treatment was repeated and she improved again. The two women with Hodgkin's disease are in good condition, and the children are normal and healthy. A sixth patient, a 42-year-old pregnant woman with cancer of the tongue, was given treatment with the 5 gm. radium pack through the right mandibular, right submental, and left mandibular areas. A total of 37,500 mg.·hours was given to each area. There was a fair response to treatment, and the patient was delivered of a normal full-term infant. Two months after the delivery and after repeated radium pack treatment, there was localized and general improvement. The procedure to follow in a woman with a malignant lesion who is also pregnant depends on the extent and character of the malignant lesion and the stage of the pregnancy. Irradiation over the unborn fetus at an early state necessitates immediate therapeutic abortion. Irradiation to other parts of the body does not necessarily affect the well-being of the fetus. Because of the known stimulative effect of pregnancy on malignant tissues, women who have a malignant condition should not become pregnant and should be sterilized to prevent pregnancy. Irradiation of a pregnant uterus should be avoided. When this precaution is followed, children born of irradiated mothers are normal in every way.

Hexamethonium Chloride in Hypertension.—Hexamethonium chloride in doses of 1 to 4 gm. daily was given orally for from 2 days to 10 weeks to 15 patients with moderate to severe hypertension. The dose of the drug and the duration of treatment in each patient were determined by the degree of hypertension, the response to therapy, and the toxic reactions observed. Two of the 15 patients obtained excellent results, 1 good result, and 3 fair results, while 9 were therapeutic failures. Administration of the drug was discontinued in 12 of the 15 patients because of severe side-effects, such as blurred vision, vertigo, impotence, difficulty in urination, and constipation. Increased headache, vomiting, abdominal pain, perianal inflammation, dermatitis, and tinnitus were also noted. Two patients developed paralytic ileus, one of them after receiving 1 gm. of the drug for only two days. The toxic reactions of hexamethonium chloride overshadowed its beneficial effects. The magnitude and severity of the toxic reactions were unrelated to the dosage of the drug, there being pronounced variation in tolerance from patient to patient. Caution should be exercised in its use, and hospitalization is advisable.

Detecting Salt Depletion During Cardiac Therapy.—The low salt syndrome is a dangerous complication in the management of congestive circulatory failure, but it is not always correctly identified. Silverman describes a practical method for detecting this syndrome, which does not require complicated laboratory procedures. The method depends on observing the response of the urinary chlorides and the change in body weight following the administration of a test dose of a mercurial diuretic. Ordinarily, the diuresis obtained from mercurials results in a profuse excretion of chlorides and a loss of body weight. If, on the other hand, a depression of the urinary chloride is observed and at the same time there is a prompt gain or no loss of weight, the low salt syndrome should be suspected. At the start of the test the patient's weight is noted and a sample of urine is obtained. The diet remains unchanged, and the patient is urged to take fluids.

A test dose of 1 cc. of one of the standard mercurial diuretics is administered intramuscularly. All urine is collected for four or eight hours and measured and tested for chlorides. A kit containing a test tube, a dropper, a 10% solution of potassium chromate, and a 0.73% solution of silver nitrate is all the equipment needed. The test is performed by placing 10 drops of urine in a test tube and adding 1 drop of the potassium chromate solution. A yellow-orange color is produced. To this mixture the silver nitrate solution is added drop by drop—the number of drops being counted—until the color changes to a reddish brown. Each drop of silver nitrate solution required to produce this color change represents 150 mg. of chloride per liter. The average person will normally demonstrate over 3 gm. (that is, 20 drops of the silver nitrate solution is required). A patient with the salt depletion syndrome will have extremely low levels of chlorides in the urine, often as low as 150 mg. (1 drop). In managing cardiac patients with a low salt diet and mercurial diuretics, testing the urine daily for chlorides yields important clinical data and should be more widely practiced. In collaboration with another investigator the author described in another paper a rapid bedside method for estimation of the serum chlorides in patients with the salt depletion syndrome.

Accidental Visualization Months After Intracranial Injection of Thorotrast.—A case is described in which the lateral ventricles and the third ventricle were visualized about eight months after the injection of colloidal thoriumdioxide (Thorotrast) into a cerebral cavity not communicating with the ventricles. While the most likely explanation for the visualization is a deposit of the contrast medium, how this occurred is not evident. The cavity in the brain was distinctly lateral to the left lateral ventricle, as demonstrated by the pneumoencephalogram made nine days after the injection. At least at that time, there was no communication of the cavity with the ventricle. It appears possible, however, that an accidental penetration of the ventricle occurred when the serosanguinous fluid was aspirated from the region of the left temporal lobe. A possible explanation for the presence of the contrast medium in the ventricles after such a long period is that it had lost its colloidal properties from having been in a closed cavity (as indicated by the work of Freeman), and when it was then accidentally transferred to the ventricles it clung to the walls much more readily. It seems more plausible that it reached the ventricles directly rather than leaking out and eventually getting into the ventricles by way of the subarachnoid spaces.

One other possibility was considered initially before the history of instillation of the contrast medium into the cavity in the brain was obtained, namely, calcification of the walls of the lateral and third ventricles. It seems likely that calcium is present at the site of the intracerebral hematoma, with possibly some of the contrast medium at this site also.

The Detection of Chromosomal Sex in Hermaphrodites.—In humans, females have an XX chromosome combination while males have XY chromosomes as the sex chromosomes. Moore and associates point out that, according to the Klebs classification, there are true hermaphrodites and pseudohermaphrodites. The criterion of true hermaphroditism is the presence of ovarian and testicular tissue, either as an ovotestis or as a separate ovary and testis. Such cases are rare, about 50 histologically proved cases of true hermaphroditism having been recorded in the literature. Pseudohermaphrodites are classified as "male" or "female" according to whether the gonads are testes or ovaries. As in true hermaphrodites, pseudohermaphrodites show great variation in the genital structure, body form, breast development, growth of hair, and psychosexual manifestations. Pseudohermaphroditism appears to be commoner than is usually thought, the incidence being, according to Young, 1 in 1,000 of the population. The secondary sex characteristics in pseudohermaphrodites often run counter to the type of gonad. The authors stress the desirability of a more reliable identification of hermaphrodites. They have found that the nature of the sex chromosomes (XX or XY) may be detected by examining the epidermal nuclei in a small biopsy specimen of skin. They describe preliminary investigations on animals (cats) that led to the detection of chromosomal sex in man from skin biopsy specimens. A study of skin specimens from 50 women and 50 men of normal sex development demonstrated a difference in nuclear structure, according to sex, in cells of the malpighian layer. Nuclei of female specimens contain a mass of sex chromatin, which is seldom seen in the nuclei of male specimens. The sex chromatin is believed to be derived from heterochromatic parts of the sex chromosomes. The XX chromosomes of the female produce a chromatin mass large enough to be identified, while the XY chromosomes of the male do not produce a chromatin mass large enough to be distinguished from the general particulate chromatin. This method of detecting the chromosomal sex has been used in two cases of hermaphroditism. One patient proved to be a chromosomal female and the other a chromosomal male. The extension of this study to other cases of intersexuality is urged in the hope of clarifying the complex problem of hermaphroditism. The potential importance of the skin biopsy technique lies in the possibility that it may prove to be a simple method of detecting the dominant sex in infancy in doubtful cases.

Relation of Nipple Discharge and Papillary Disease to Cancer.—Kilgore and associates discuss the relation of nipple discharge and cancer on the basis of their observations on 190 patients with nipple discharge and of reports in the literature. A secretory discharge that is either grossly milky or contains secretory elements microscopically is of little significance and requires no more than observation for change of character. A serous discharge without secretory elements will contain blood at some time in one-third or more of the cases. The significance of such a discharge is similar to that of one containing blood. When there is a bloody discharge without a palpable lump, the chance of cancer being present is about 1 in 20 to 1 in 25. For this reason alone the source of bleeding should be found and its nature determined. If cancer is not present, bleeding may arise from papillary disease. There is disagreement as to the relationship of papillary disease to cancer. The authors feel that papillary disease indicates a cancer risk greater than average. None of the methods of locating and removing a single lesion of papillary disease is uniformly successful. If such a lesion is found, the chance of leaving undiscovered lesions elsewhere in the breast is considerable. For these reasons the woman over 40 with a bloody discharge or papillary disease and younger women with multiple lesions should be subjected to mastectomy (extended to radical operation if cancer is discovered).

Treatment of Pancreatic Cysts.—The relation of pancreatitis to pancreatic cysts is well established. The concept that recurrent pancreatitis usually results from the retrojection of bile into the pancreatic duct has been supported by the experience of the authors of this report. This can occur only if the sphincter of Oddi is spastic and when the bile and pancreatic ducts join in a common ampulla above the papilla of Vater. The presence of this common passageway in the described cases of pancreatitis and the good results achieved by sphincterotomy support this concept. Patients with inflammatory cysts must have spasm of the sphincter of Oddi, which tends to perpetuate or increase the pancreatic cysts. Drainage of these cysts must continue for long periods, because the pancreatic intraductal pressure is higher than normal because of the sphincter spasm. For the same reason pancreatitis may recur even in the presence of a draining pancreatic fistula, as is illustrated in two of the cases described here, and in the literature. Drainage does not prevent recurrences of pancreatitis and formation of new cysts, as was observed in one of the reported cases. Sphincterotomy should not only be helpful in the treatment of pancreatic cyst but also, by removing the cause of pancreatitis, should prevent further attacks. Although cystogastrostomy and cystojejunostomy have given good results, it does not seem advisable to anastomose the gastrointestinal tract to a retroperitoneal space; the authors do not consider it necessary except in cysts of the head of the pancreas in which the wall, probably a dilated duct, is hard and rigid. Since acute pancreatitis with pathological changes can occur with few or no overt clinical symptoms, it is not surprising that pancreatic cysts are found without a history of gastrointestinal disease. Such cysts, unless they are of congenital origin or due to an adenomatous growth, must have been caused by pancreatitis. Traumatic injury of the pancreas may produce necrosis of pancreatic tissue and rupture of the ducts. Since the pathological process following such injury is similar to that following acute pancreatitis, any cyst that may result should be treated similarly. The authors arrive at the following conclusions: 1. Pseudocysts of the pancreas, of inflammatory origin, should be treated by drainage and by section of the sphincter of Oddi, since this will cure the cyst and prevent the recurrence of pancreatitis. 2. Persistent cutaneous pancreatic fistulas resulting from drainage of a pancreatic cyst should be treated by sphincterotomy. 3. Cysts of the head of the pancreas should be treated by cystojejunostomy and sphincterotomy.

Preservation of Living Bone in Plasma.—Tucker found that a bone of a dog could be kept in the serum of the host at a mean temperature of 5 C (40 F) for as long as 18 months and be transplanted into other dogs with success. Similar methods were used for human bone. The bone was obtained from fresh cadavers not longer than six hours post mortem or from amputated extremities. These bodies were free from apparent infection or malignant disease. The blood Wassermann reaction, blood group, and Rh factor were determined. The bone was removed with sterile technique and placed in a sterile container, which was then filled with human plasma; 3 gm. of sodium sulfathiazole and 1,000,000 units of soluble penicillin were added to each 1,000 cc. of plasma. The containers were kept at a mean temperature of 5 C (40 F). The plasma was cultured at intervals, but only one specimen was found contaminated with a fungus after 14 months of storage. Microscopic, chemical studies, and tissue cultures were made on bone preserved in this manner. It was found that the cellular elements of this bone remain intact for long periods. The osteocytes of the bone show histological evidence of viability for as long as 28 months. Chemical changes take place when bone is stored in homologous plasma that do not occur when bone is preserved in heterogenous plasma. This type of preserved bone has been used in 40 cases. In no instance was there a postoperative infection or nonunion of the graft. In one patient, who was operated on six weeks after grafting, the graft was firmly united to the bone. Roentgenologically these grafts are well united at six months. Large quantities of viable bone that possesses osteogenic properties can be preserved by this method.

Intrathoracic Meningocele.—Two cases of intrathoracic meningocele are described because of the extreme rarity of this lesion. One of these cases was diagnosed preoperatively, which is rarely done because the condition is commonly mistaken for a posterior mediastinal neurofibroma with an intraspinal hourglass extension. In both of the reported cases the meningocele was successfully removed with complete recovery. Including these two cases, a total of 15 proved intrathoracic meningoceles have been reported in the literature. Von Recklinghausen's disease or cutaneous neurofibromatosis was associated with this anomaly in 9 of the 15 cases, and there were associated spinal deformities in 13 of the 15 cases. Since 1948, a total of six meningoceles have been successfully removed without a death. The seventh patient operated on died of cardiac arrest. Previous to 1948, the mortality following surgical removal was 100%. The indications for the surgical removal of intrathoracic meningocele are progressive enlargement of the meningocele, compression of intrathoracic structures and progressive erosion of the associated spinal vertebrae.

Problem of Immunologic Agranulocytosis.—Severe agranulocytosis in the blood and bone marrow associated with a pronounced increase in the percentage of gamma globulins is reported in a 63-year-old woman. The cause could not be established with certainty, but drugs as the causative agents could be eliminated. Corticotropin in doses of 20 mg. was given every six hours together with salt-free diet and potassium, causing depression of gamma globulins well correlated to the clinical and the hematological cure. Some sodium retention necessitated discontinuation of corticotropin therapy for one day, resulting in a relapse with an increase in gamma globulins and a pronounced decrease in leukocytes. The author speculates that the "idiopathic" agranulocytosis in this patient represented a leukocytic "variant" of immunologic hemolytic anemia, and that the cause is in some abnormality of the antigen-antibody response of the body.

Estrogen Treatment of Prostatic Carcinoma.—Fergusson and Franks report studies on tissue obtained on two or more occasions from the same patient with prostatic cancer treated with estrogens (5 to 30 mg. of diethylstilbestrol or the equivalent daily) and followed for nine years. Tissue was obtained by repeated biopsies or by biopsy and subsequent postmortem examination. Biopsy material was removed by a suitable needle through the perineum, at periurethral resection, or at open operation. Occasionally it was possible to examine serial biopsy specimens from accessible metastatic lesions in lymph nodes or bone. In all 82 specimens from 33 patients were available for study. Paraffin sections stained with hematoxylin and eosin were examined by one of the authors, and in some cases sections were stained for elastic tissue (orcein), reticulin (Foot's method), or by a modification of Masson's trichrome method. It was found that clinical regression of primary prostatic carcinoma after estrogen therapy is associated with histological evidence of cell destruction in the prostate. In almost all cases the tumor cells, but not the normal tissue, eventually lose their sensitivity to the hormone. The reason for this is not known, but a relative loss due to inadequate dosage occurs in some cases. The resistant tumor cells have no specific histological characteristics but are often of the dark-cell type in solid trabeculae. Even in cases with a very marked histological response to estrogens there are always surviving tumor cells, so that it is unlikely that endocrine treatment alone can ever be expected to "cure" prostatic cancer. Grading is of little value in assessing the prognosis or response to treatment, as estrogen sensitivity of the tumor cells is independent of the degree of differentiation or anaplasia. The presence of metastases when the patient is first seen tends to reduce the survival period. Breast tissue changes associated with administration of estrogens is often associated with a good clinical response. The optimal dosage of estrogens may be higher than that generally used. The subjective response, the behavior of the primary growth and accessible metastases, and the development of breast swelling and other side-effects indicate that in many cases doses of from 5 to 10 mg. of diethylstilbestrol may be sufficient to produce an initial effect over a few days. In others, three to four weeks may elapse before any change is noted, and in some the condition appears entirely unresponsive. The use of other hormones, such as pituitary hormones, is being investigated in cases in which the prostatic tumor has become estrogen-resistant.

Bilateral Carcinoma of Breast.—Twenty of 504 patients with cancer of the breast who were treated at St. George's Hospital in London between 1938 and 1951 had bilateral growths, and in 15 of them there was clinical and histological evidence that both were distinct primary tumors. The remaining five were advanced cases in which the possibility of spread from one breast to the other could not be excluded. Despite the extreme rarity of multicentric cancer and the frequency with which bilateral tumors have been ascribed to metastasis, there is evidence that in the first 15 cases of the present series the second growth was a primary carcinoma, In seven of the cases the growths were morphologically very different, and in five other cases the second tumor was clearly seen arising from an intraductal carcinoma. In the remaining three cases, as in most of the others, there was clinical evidence that both tumors were primary. The author concludes that bilateral breast carcinoma is due oftener to two primary tumors than to dissemination of a single growth.

Emphysema Treated by Pneumoperitoneum.—The essential pathological feature in emphysema is loss of elasticity in the lungs, which are very large but not truly distended. Expiration, largely a passive process produced by recoil of the elastic tissues of the lung, is impaired. The patient is unable to ventilate the lungs, and the oxygen saturation of the arterial blood falls to 85%. The inspired air tends to be drawn into the dead space formed by dilated and avascular alveoli. Chest expansion is often less than 1 in., and the increase of carbon dioxide in the blood produces dyspnea, often accompanied by cough and bronchospasm. Myocardial failure may also occur. Nine patients with severe pulmonary emphysema were treated with pneumoperitoneum and encouraging symptomatic relief was obtained in six. The purpose of this treatment is to raise the intra-abdominal pressure sufficiently to cause elevation of the diaphragm during expiration without impeding its contraction during inspiration. The excursion of the diaphragm is increased, and pulmonary ventilation is improved. The amount of air required by each patient can soon be determined; in this series, 400 cc. were given initially and the volume was gradually increased until from 800 to 1,000 cc. could be given without discomfort. Thereafter refills were given at weekly or biweekly intervals. Minor degrees of ascites occurred, and in one case inguinal hernias were aggravated. A few patients complained of abdominal discomfort for the first 24 or 48 hours after a refill, usually because too much air had been given. Improvement was shown by the disappearance of dyspnea and an increase in the amount of exercise that could be taken. Two of the three patients who were not benefited had a history of congestive heart failure and the other had asthma. Bronchitis, to which emphysematous patients are particularly subject, temporarily nullifies the good effects of a pneumoperitoneum.

Proteolysis in Gastric Anacidity.—In an attempt to explain the part played by gastric kathepsin in the satisfactory proteolysis frequently observed in patients with gastric anacidity, the patients were given 500 cc. of skimmed milk after the gastric juice had been aspirated by tube from the fasting stomach. After 15 to 20 minutes a moderate amount of chyme was removed, and its tryptophan, tyrosine, residual nitrogen, and total nitrogen contents were determined. Ten minutes after the administration of the usual alcohol or caffeine test potion, the peptic proteolysis at 1.8 pH and the katheptic proteolysis at 3.8 pH were determined with the aid of the nephelometric edestin method. The proteolytic activity of ferment preparations was ascertained by the biuret method determining photometrically the split peptide compounds according to the decreased extinction. Two types of patients with gastric anacidity could be distinguished; the first group consisted of patients whose gastric mucosa still functioned but with reduced secretion of pepsin and kathepsin, and group 2 of patients with long-standing anacidity and atrophic gastric mucosa in whom the production of gastric ferments had almost stopped. In patients of the second group considerable regurgitation of the duodenal juice as well as satisfactory proteolysis was usually observed. The katheptic component could not have been responsible for the proteolysis, since such secretion was absent. It is suggested that the regurgitated tryptic ferments are responsible for the satisfactory proteolysis; these ferments may be exclusively responsible in patients with atrophy of the mucosa, and combined with the katheptic ferments in patients with a reduced production of gastric ferments. Patients with gastric anacidity and disturbed proteolysis were given a therapeutic trial with 1 gm. of glutathione, resulting in further reduction of proteolysis almost to zero. This almost complete arrest of the proteolysis was considered to support the author's concept that in patients with gastric anacidity and atrophy of the gastric mucosa proteins are broken down by tryptic catalysis. Experiments with commercial pancreatic preparations whose activity was determined by the biuret method revealed a rapid increase of the proteolytic activity between pH values of 6 and 7, with results not much below the optimum in the neutral range. These findings suggest treatment with pancreatic ferments or trypsin preparations as the method of choice in patients with gastric anacidity and atrophy of the gastric mucosa.

Arterial Extract in Arteriosclerosis.—Telatuten, an organic preparation extracted from the wall of the arteries of young animals and containing the active substances of the three coats of the vessel, was used to treat 14 patients with arteriosclerosis. Six patients in whom the disease involved mainly the legs (claudicatio intermittens) received intravenously 1 cc. of the drug daily for 6 days or every other day for 15 days. There was a one week treatment-free period after the patient had received 6 cc. when the therapy was continued longer. Sometimes oral administration of four 0.5 gm. tablets of Telatuten daily followed for 10 to 20 days. The improvement of insomnia, headache, irritability, and mental confusion was pronounced in three patients and moderate in two, but the condition of one patient remained unchanged. There were no side-effects, and in a follow-up six months later the improvement was still present. Five patients with arteriosclerosis and arterial hypertension received the drug intravenously and intramuscularly (1 cc. daily) and then orally (four to six 0.5 gm. tablets daily). The systolic pressure and sometimes the diastolic pressure dropped in four patients, insomnia, headache, and memory disturbances disappeared in all five, and the electrocardiographic and ballistocardiographic findings were improved. The drug was given to three patients in whom arteriosclerosis was associated with angina pectoris. The patient in whom the angina was severest received the drug intramuscularly for six days, while glyceryl trinitrate had to be given concurrently. Then Telatuten was given intravenously in two 10 day courses. The anginal attacks became less frequent and less severe, administration of glyceryl trinitrate was no longer necessary, and the blood pressure dropped. The other two patients received Telatuten intravenously in three four-day courses, with a treatment-free interval of four days between each course. Their general condition was improved, and the precordial distress that usually followed the slightest exertion and preceded the anginal attacks was no longer present. The drug restored to normal the cholesterol values of patients with cholesteremia. Telatuten probably influences the arteriosclerotic picture by interfering with the cholesterol metabolism, which is one of the main pathogenetic factors of the disease.

Mephenesin in Hemiplegia.—Mephenesin (Tolseron) was used to treat four patients with spastic hemiplegia. Cerebral thrombosis had occurred in one of these patients 10 months earlier, and a cerebral hemorrhage in another 2 months earlier. The other two were hospitalized immediately after the attack, and the therapy was instituted 21 and 40 days later respectively. The initial dose of mephenesin was 1 gm. daily, but this was gradually increased every three to four days thereafter to the average effective daily dose of 3 gm. From 34 to 282 gm. of mephenesin were given to each patient over a period of from 22 to 88 days. No other drug was given concurrently. Passive mobilization of the paralyzed extremities, with psychological and physical reeducation for voluntary movements, was practiced. The patient who was treated earliest regained active mobility completely and two others improved satisfactorily. All three regained the voluntary movements of the muscles of the trunk and leg before those of the arm and hand. Results were limited in the patient to whom mephenesin was given many months after he had suffered the cerebral thrombosis. The good results obtained were still present in the patients two to eight months after discontinuation of the therapy. Mephenesin was also given to seven patients with flaccid hemiplegia, one of whom had had a thrombosis, one an embolism, and five a cerebral hemorrhage. The same daily doses of mephenesin were used as for the patients of the first group. A total dose of from 25 to 95 gm. of the drug was given over a period of from 18 to 40 days. Despite the complication of bronchopneumonia, one patient who received the drug 38 days after the attack regained 75% of the voluntary movements in 40 days; there was, however, contracture of some groups of muscles in the extremities. The paralysis regressed almost entirely in another patient in whom the therapy was instituted 30 days after the attack. Two of the patients, who were treated earlier, regained normal mobility in 20 and 25 days, respectively, although some muscle contractures appeared and were still present at the time of writing. All patients regained normal ambulation and good function of the arm. The good results were still present two to six months after the treatment was discontinued. The drug prevented the appearance of extensive muscle contractures and brought about in each patient as much functional restoration as could be expected considering the anatomic lesion present.

Mitral Stenosis.—Of 200 patients subjected to thoracotomy for mitral valvular disease, 130 came from one medical unit. This paper is concerned with the first 100 of these 130, in whom valvulotomy was performed for mitral stenosis. Patients with mitral stenosis of all grades of severity were included, except those without symptoms and those with very large hearts and uncontrollable cardiac failure. In the absence of contraindications, surgery should be considered for every patient with mitral stenosis in whom symptoms are progressive. In distinguishing predominant stenosis from predominant incompetence, the qualities of the first heart sound and the opening snap are emphasized. Radiography is indispensable. Electrocardiography sometimes gives useful evidence. Cardiac catheterization may be valuable in difficult cases. Patients with the highest pulmonary arterial pressures tend to have a high pulmonary arteriolar resistance, advanced mitral stenosis, normal rhythm, right ventricular hypertrophy, recurrent hemoptysis, and breathless attacks but no pulmonary edema; they seldom have auricular fibrillation. A relatively low pulmonary arterial pressure may be due to severe myocardial damage. Auricular fibrillation, which existed in 40% of the patients, is a disadvantage but not a contraindication to operation; auricular fibrillation developed in 19% who had sinus rhythm before operation in the postoperative period. Sinus rhythm can be restored with quinidine. Pregnancy often aggravates mitral stenosis. Valvulotomy is sometimes an alternative to the termination of pregnancy; the results in three such cases are reported. The outstanding risk of the operation is embolism, but cardiotomy may permit evacuation of a clot from the left auricle and atrium without production of systemic embolism. Seven patients died as a result of the operation. The causes of death were embolism, ventricular fibrillation, transfusion reaction, cardiac arrest, probable hepatic failure, and probable intracardiac thrombosis. In 74 patients followed for more than three months, the results were good in 66, fair in 6, and poor in 2. In one of the patients with a poor result a second operation achieved better division of the commissure. In patients with intractable edema, ligation of the inferior vena cava may prove to be useful before valvulotomy is done. Valvulotomy is not curative, and changes in cusps, chordae, and cardiac muscle will persist.

*Increased Lead Absorption Resulting from Pica in a Boy Aged 7, Combined with Gastric Achylia and Hypochromic Microcytic Anemia. C. J. van Wisselingh and C. de Kruijff.—p. 128.

Increased Lead Absorption Resulting from Pica.—A 7-year-old boy had severe hypochromic microcytic anemia, splenomegaly, and gastric achylia. For three years the boy had repeatedly eaten lead paint. Signs of malnutrition had existed for a long time. Despite the pica (eating of lead) the boy showed no symptoms of lead poisoning. In this connection, the authors stress the difference between increased lead absorption and lead poisoning. The latter is usually characterized by encephalopathy, neuritis, paralysis, and intestinal colics. None of these symptoms were present in the boy. His severe anemia might have been caused by the lead intake or by deficient nutrition. It is unlikely that the achlorhydria was the only cause of his hypochromic anemia. Possibly intestinal disturbances were partially responsible. Psychic factors may also have played a part, and these in turn may have caused anorexia, with the result of deficient food intake, so that a vicious circle was created. It is difficult to say which factor was primary. Achlorhydria combined with hyperchromic anemia occurs oftenest in women. Women with chlorosis frequently have pica.

Effects of Shoes on Foot Form.—Knowles shows that the measurement of feet, training of shoe fitters, and use of x-ray equipment cannot compensate for the gross discrepancy between the triangular outline of the plantar aspect of the natural foot and the unrelated, pointed, tapering, or rounded outlines of modern shoes. The experiment described was based on the assumption that modern shoes distort the feet, and was designed to ascertain the reversibility of such distortion. Shoes of a suitable size were not made "to measure" or "to fit" in the conventional sense but rather to the shape and proportions that would fully accommodate natural feet. Special lasts had to be constructed, which were given a triangular plantar aspect. They were of suitable length and of average shape and width. Several pairs of shoes were made on these lasts and have been worn for three and a half years to the exclusion of all other shoes. X-ray photographs of the feet were taken on the day of the permanent change-over in August, 1948. By checking the external appearance of the feet against a photograph taken at the time of the change-over, it was noticed that no remarkable change occurred for many months. The wearer of these shoes was 37 years old, and rapid skeletal changes were therefore hardly to be expected. By November, 1950, however, some change was noted, and an x-ray picture taken then showed that the toes had become less cramped. The experiment was concluded with final x-ray films taken in April, 1952. The valgus tendency of the hallux of the right foot was corrected. The left hallux, though it had less valgus tendency originally, has not improved so much; the osteoarthritic changes in its metacarpophalangeal joint already shown in the earlier x-ray films are unaltered. Spread of the smaller toes has improved only to a slight extent. Excessive perspiration ceased immediately in the new shoes, the epidermophytosis eventually cleared spontaneously, and the onychocryptosis, though still present to a degree, ceased to be troublesome.

Effects of C 7337 (Regitine) on Patients with Arterial Hypertension. T. A. Capris and S. A. Plesch.—p. 109.
*Precocious Sexual Development in Infant Three Months Old Due to Tumor of Third Ventricle. L. F. Diez, J. J. Staffieri and J. E. Celoria. —p. 116.

Eosinophils and Lymphocytes in Arterial Hypertension.—The absolute amount and differential count of circulating eosinophils and lymphocytes were determined in 35 patients with essential hypertension, and the eosinophil response to epinephrine and corticotropin (ACTH) was observed. The epinephrine test was also carried out in 16 dogs, who either had experimental nephrogenic hypertension of more than six months' duration or were normal. The patients were considered in two different groups. The 19 patients of the first group had essential hypertension of either grade 3 or 4. All had hypertensive cardiopathy without cardiac insufficiency. The renal function was impaired in four patients. The 16 patients in the second group had essential hypertension of either grade 1 or grade 2 without cardiac or renal insufficiency. The results were as follows: The level of circulating eosinophils was low but within normal limits in all patients in both groups. The number of the circulating lymphocytes was also low but within normal limits. They were lower in the patients of the first group than in those of the second group. The circulating eosinophils decreased following the epinephrine test more than 50% in all of the patients in both groups. The response to corticotropin was normal in the three patients with hypertension of grade 3 or 4. Epinephrine eosinopenia was much more marked and of longer duration in dogs with nephrogenic hypertension than in the controls. The authors believe that in patients with essential hypertension the secretion of corticoids, the response of the hypophysis to the stimulation of epinephrine and corticotropin, and the response of the cortex to the hypophysial stimulation are normal. The acute eosinopenia observed in dogs with nephrogenic hypertension shows that in this experimental condition the adrenal glands undergo pathological changes that result in increasing the sensitivity of the hypophysioadrenal system to epinephrine.

Precocious Sexual Development Owing to Ventricular Tumor. The subject of this report was an infant, 3 months old, who had two attacks of convulsions within a month. The patient showed signs of increased intracranial pressure and marked muscular hypotonia. The head was enlarged, and the infant was unable to hold it in normal position when taken in the arms. The testicles were as large as those of a 3-year-old child. The coexistence of the neurological and endocrine syndromes and the isosexual type of precocious sexual development suggested a tumor in the third ventricle as cause of the syndrome. The diagnosis was confirmed by encephalography and ventriculography. The operation consisted in removing a small tumor from the wall of the third ventricle. The tumor on histological examination proved to be an astrocytoma. The neurological and endocrine symptoms regressed after the operation. The patient was well three years after the operation.

*Importance of Study of Blood Coagulation in Patients with Cardiac and Vascular Diseases. F. Weis.—p. 1153.

Blood Coagulation in Patients with Cardiovascular Diseases.—Blood coagulation was studied in patients with cardiovascular disease with the Waugh and Ruddick in vitro heparin tolerance test. There was hypercoagulability in four of five patients with venous or arterial thrombosis, and it was more pronounced in the three patients with venous thrombosis. Marked hypercoagulability was also revealed in one of three patients with myocardial infarction in whom the test was performed 15 days after the onset of the symptoms. Normal values were found in the other two, in whom the test was performed 19 and 32 days, respectively, after the symptoms had appeared. There was hypercoagulability in one patient with coronaritis associated with angina pectoris. The test was also performed in 18 patients with cardiac insufficiency who were receiving digitalis. The results indicated normal coagulability in six patients regardless of the type of insufficiency, hypocoagulability in six patients with right-sided cardiac insufficiency and one with left-sided insufficiency, and hypercoagulability in five patients. Hypercoagulability was attributed to chronic cor pulmonale in one patient and administration of a mercurial diuretic in another. In the other three the cause of the hypercoagulability was not clear, unless it could have been ascribed to a thrombotic process that had formed in some area that could not be explored clinically. The author performed the test on eight patients with diseases that do not affect blood coagulation (pneumonia, pulmonary abscess, and nephritis) who were receiving penicillin. The heparin tolerance curve indicated hypercoagulability in all of them, revealing the effect of the antibiotic on the blood coagulation. This test generally reveals hypercoagulability in patients with arteriosclerosis. The in vitro heparin tolerance test should always be made on patients with cardiac and vascular diseases before any anticoagulant therapy is instituted.

*A New Antibiotic: Erythromycin. B. Mathieu de Fossey.—p. 687.

"Recent Lesion" Factor in Isoniazid Treatment of Pulmonary Tuberculosis.—The effect of isoniazid on pulmonary tuberculosis was studied in 414 adult patients, 215 of whom had had the disease for more than six months (group 1). The other 199 patients (group 2) had either had it for less than six months so far as could be determined, or had recurrences superimposed on former lesions. The importance of early treatment was shown by the differences between the results obtained in the two groups. Reduction of fever and a gain in weight are easily discernible, and in these respects the differences between the two groups were moderate. The temperature was reduced in approximately 10% more of the patients in group 2, and was restored to normal in from 15 to 25% more, while weight gains were recorded in approximately 15% more of the patients in group 2. Much greater differences were revealed when the results of bacteriological and x-ray studies were compared; thus negative cultures were obtained at the end of three months in 73% of the patients in group 2 and in only 35% of those in group 1. Significant improvement in the radiological picture was seen in two-thirds more of the patients in group 2 than of those in group 1. Prolongation of isoniazid treatment for more than three months often produces continued improvement and may result in cure; sometimes, however, the action of the antibiotic must be supplemented by pneumothorax or some other form of surgical treatment. The use of streptomycin or *p*-aminosalicylic acid in combination with isoniazid lessens the danger that drug resistance will develop as a result of prolonged treatment. New cases of pulmonary tuberculosis should be treated as emergencies; delay in instituting treatment may lead to a chronic illness resistant to therapy.

Cerebrovascular Stroke.—Treatment of cerebral stroke of vascular origin should be designed to prevent or reduce edema, which, apart from massive hemorrhage, is the principal cause of death in this condition. All patients should be treated with continuous intravenous infusion of isotonic sodium chloride solution with glucose, 500 cc. in 8 hours, to which 40 cc. of 1% procaine (Scurocaine) hydrochloride without epinephrine and 1 ampul of Phenergan (10-[2-dimethylamino-1-propyl] phenothiozine) have been added. The isotonic sodium chloride solution with glucose should be replaced by 250 cc. of hypertonic 30% sodium chloride solution with glucose for patients with renal disease, and diabetics should be given isotonic sodium chloride solution without glucose. A substance capable of correcting cellular fragility, as for instance 5 cc. of 2.5% soluble rutin, may also be added. This basic treatment should be supplemented by heparin and stellate infiltration if softening is unquestionably present, or thrombase if hemorrhage is known to have occurred. Powerful ganglion blocking agents may prove helpful in severe cases in which the condition progresses without remission; if no improvement occurs, surgical intervention may be tried. Surgical removal of intracerebral hematomas will be successful in two out of three young patients and in one out of three older ones. Careful nursing and specific etiological treatment, such as insulin for diabetic patients, must not be neglected.

Erythromycin.—Erythromycin is a nontoxic antibiotic that is very effective against many bacteria, especially gram-positive organisms such as the pneumococci, the staphylococci, and various hemolytic and nonhemolytic streptococci. The fact that erythromycin must be given orally, because it is not readily soluble in water, makes its administration convenient and easy. It is perfectly tolerated in therapeutic doses and no complications affecting the kidneys, ears, liver, or blood as a result of its use have yet been reported. Mild digestive disturbances sometimes occur, but then disappear when administration of the drug is suspended. Contact with gastric juice reduces the activity of erythromycin, which is strongly alkaline, and its absorption is delayed and reduced when there is food in the stomach. The average initial dose is 1.5 to 2 gm. every 24 hours, given in four doses at six hour intervals, as far removed from mealtimes as possible. Smaller doses may later be used for maintenance. Erythromycin has been used effectively in diseases of the lungs, endocarditis caused by Streptococcus viridans, benign lymphogranulomatosis, and various other infections. It occupies a place between the broad spectrum antibiotics, such as aureomycin and oxytetracycline (Terramycin), and penicillin, and is especially valuable as a substitute for penicillin in cases of penicillin resistance.

*The Treatment of Roentgen Intoxication with Dihydroergotamine. K. Werner.—p. 431.

Dihydroergotamine in Treatment of Intoxication Resulting from Irradiation.—Roentgen intoxication is particularly severe when the sympathetic nerve is irradiated. It results from the action of roentgen rays on the neuroglandular system, from the resulting changes in the vegetative processes, and from tissue changes that in turn affect the sympathetic system. Werner found the various suggested remedies inadequate, including vitamins, circulatory remedies, belladonna, and liver preparations. He warns against the use of vitamin B_{12}, because its growth-promoting character may prove deleterious in tumor patients. In his search for a more effective remedy for roentgen intoxication, he decided to try dihydroergotamine, which was available in a drop solution for oral administration and in ampuls for injection. He usually prescribed 10 or 20 drops three times daily. Symptoms of roentgen intoxication appeared in 298 of 1,515 patients subjected to roentgen therapy, that is, in less than one-fifth. In view of this relatively low incidence, it is considered inadvisable to institute general prophylaxis against roentgen intoxication. Therapy was begun only if symptoms of roentgen intoxication appeared. The author compares the results of treatment with dihydroergotamine with the results of use of sedatives, vitamin B complex and belladonna. Dihydroergotamine is definitely superior to other agents. Dihydroergotamine not only proved the most efficient remedy for roentgen intoxication but also improved tolerance for nitrogen mustard therapy.

Investigations on So-Called "Large Bodies" in Green Streptococci. W. Bommer.—p. 510.

Isolation of Tubercle Bacilli After Pretreatment with Sulfuric Acid.—Because of the slow growth of tubercle bacilli, destruction of the accompanying bacteria is of vital importance if tubercle bacilli are to be obtained in pure culture. Weigand cites reports in the literature indicating that different concentrations of sulfuric acid have been used chiefly for this purpose, but there is no agreement on the concentration of the sulfuric acid nor on the length of exposure. To obtain more definite information about this, studies were made with various concentrations of sulfuric acid at the Hygiene Institute, on the sputum of 60 patients with established pulmonary tuberculosis. It was found that in tubercle bacilli cultures the accompanying bacteria can be destroyed by preliminary treatment with a 6% concentration of sulfuric acid. The specimen is treated with this concentration for 20 minutes, during which the mixture is shaken several times. Then it is centrifuged for 10 minutes at 2,500 to 3,000 rpm. Treatment with higher concentrations of sulfuric acid proved unnecessary; in fact, the yield improved by 37% when a 6% instead of a 10% concentration of sulfuric acid was used. Furthermore, particularly in the study of sputums and specimens of urine, growth was accelerated on the average by from 7 to 14 days. A greater incidence of positive results in urine and gastric juice specimens was obtained with the 6% concentration of sulfuric acid.

BOOK REVIEWS

Immunity: Hypersensitivity, Serology. By Sidney Raffel, Sc.D., M.D., Professor of Bacteriology, Department of Bacteriology and Experimental Pathology, Stanford University School of Medicine, Stanford University, California. Cloth. $8. Pp. 531, with illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1953.

One area in which the medical student does not get adequate training is the field of immunity and sensitivity reactions; because of this the average physician is not sufficiently familiar with immunity mechanisms and the relationships of these and of sensitization reactions to the development of disease. Probably one of the reasons for this is the lack of an adequate textbook. Most of the books on immunology and allergy do not adequately cover the field, although there are exceptions. This book gives a complete coverage of immunity processes in general. The author, who is a well-known investigator in the field, has condensed a large amount of information into a work of reasonable size.

The book has four general sections, the first of which deals with the fundamental aspects of immunity. The second takes up hypersensitivity (allergic) mechanisms. The third deals with the mechanisms of resistance in specific infectious diseases including pneumococcal disease, anthrax, plague, cholera, bacillary dysentery, tuberculosis, botulism, diphtheria, gas gangrene, smallpox, poliomyelitis, and influenza. The final section concerns various other aspects of hypersensitivity, with detailed discussion of various types of tissue and blood antigens. The book should be of value to the student and to the practitioner, as it will provide a solid foundation in immunologic principles. It may possibly be of greater value to the student, inasmuch as the emphasis is on immunology rather than hypersensitivity and its relationship to the pathogenesis of disease. This is probably only natural, as the author is not a clinician, and, possibly more important, unequivocal knowledge of the relationship of hypersensitivity to disease does not, by and large, exist.

There are a few statements or views that might be challenged, but in no case are these very serious. On page 45 the author speaks of "one chemically homogeneous antigen." It is very doubtful that anyone has ever had a chemically homogeneous antigen, if by this is meant a single molecular species, and indeed the author, in subsequent statements, indicates the improbability of such a substance. On page 223 he states, "Atopic antibody will not transfer itself to smooth muscle strips as will antibody resulting from ordinary antigenic stimuli, and the uterine muscle of a patient with atopic sensitivity shows no tendency to contract when exposed to antigen in the Schultz-Dale bath." This is a controversial statement. Schild and his colleagues have shown contraction of human tracheal muscle in atopic persons when exposed to the antigen in vitro. On page 247, in speaking of delayed and immediate types of hypersensitivity, the author states, "On the other hand, one or the other form of hypersensitivity may be present exclusively." It is doubtful that one can have delayed hypersensitivity without the concomitant presence of the immediate type, although admittedly it may be difficult to show the presence of the immediate type, which may not be involved in the development of symptomatology. On page 266 the author states, "Contact sensitization to domestic animals, for example, is found to be directed toward substances extractable by organic solvents from the dander and hair rather than to the proteins from these sources." While this is probably generally true, it certainly is not absolutely true, inasmuch as Rostenberg has reported on a woman who had intense vesicular eczematous reactions from defatted hair. The book as a whole appears to have few typographic errors. This work is an excellent introduction to the study of immune and hypersensitive mechanisms.

Textbook of Preventive Medicine. By Hugh Rodman Leavell, M.D., Dr. P. H., Professor of Public Health Practice, Harvard School of Public Health, Boston, and E. Gurney Clark, M.D., Dr. P. H., Professor of Epidemiology, School of Public Health of Faculty of Medicine, Columbia University, New York. With collaboration of George F. Badger, et al. Cloth. $8. Pp. 629, with 26 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; 95 Farringdon St., London, E.C.4, 1953.

In the practice of preventive medicine the physician is a "clinical epidemiologist," who goes beyond the patient "and concerns himself with the circumstances under which human disease is likely to develop." In his attempt to prevent disease and its ill effects he attacks the problem on five levels: "(a) Health promotion; (b) Specific protection; (c) Early recognition and prompt treatment; (d) Disability limitation; (e) Rehabilitation." Such are the basic concepts of this work on preventive medicine. Announced as "an epidemiologic approach to preventive medicine" this is a book for the practitioner, not the health officer. The physician is portrayed as the health officer of the family, responsible for analysis and correction of the physical, social, and emotional forces underlying the development of disease. At the same time the physician and patient are portrayed as part of the community, with obligations toward society as well as each other.

The volume is more philosophical than the usual textbook of preventive medicine, possibly too philosophical for the average medical student. So much attention is given to general principles and the development of "a point of view, a philosophy, and a method of approach" that there has been sacrifice of much of the detailed factual knowledge on which the philosophy is based. The volume is best suited for the practicing physician or the student near the end of medical school. Though the book is the work of 21 collaborators, it has far less of the appearance of disconnected essays than is usually found in books of this type. The senior authors have achieved a high standard of coordination and unity and have produced a work that cannot fail to open new vistas in the practice of preventive medicine.

Grundzüge der pathologischen Physiologie. Von Helmut Vogt, Professor für innere Medizin an der Universität Kiel. Cloth. 45.60 marks. Pp. 582, with 180 illustrations. Urban & Schwarzenberg, Thierschstrasse 11, Munich 22; Meinekestr. 13, Berlin W. 15, 1953.

The major divisions of this book deal with circulation (heart and vessels), blood, respiration, nutrition, digestion, the liver, metabolism, the kidneys, enzymes and vitamins, hormones, allergies, and the nervous system. The informal style reflects the author's pleasure in teaching, and the amount of space devoted to the parts of the nervous system and their integrative action is commendable. A limited list of abbreviations, which can be frustrating to foreign readers but space-saving to the author, is included. The bibliography and index are adequate, and the illustrations are clear and informative. The book can be recommended as a comprehensive, accurate, and up-to-date summary of an important subject.

Essentials of Physiological Chemistry. By Arthur K. Anderson, Professor of Physiological Chemistry, Pennsylvania State College, State College, Pa. Fourth edition. Cloth. $5. Pp. 480, with 42 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C.2, 1953.

This textbook for students with limited backgrounds in chemistry and biology, e. g., premedical students, includes a large amount of material on the chemistry of biological compounds. It is written for use with a laboratory manual. This edition includes new material on adrenal hormones, animal protein factor, antivitamins, antioxidants, carbohydrate metabolism, enzymes, folic acid, isotopes, photosynthesis, structure of starch and cellulose, and vitamin B_{12}. The book is well written, indexed, and printed.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

Radiations and Living Cells: An Introduction to Radiation Biology, in Which the Action of Penetrating Radiations on the Living Cell Is Described, with Special Reference to the Effect on Cell Division in Human Tissues. By F. G. Spear, M.D., M.A., D.M.R.E. Cloth. $3.50. Pp. 222, with illustrations. John Wiley & Sons, Inc., 440 Fourth Avenue, New York 16, 1953.

The author, a member of the Scientific Staff Medical Research Council, Strangeways Research Laboratory, Cambridge, England, attempts in this short monograph to bridge the gap between medical physics and radiation biology. This volume can be used by specialists and yet is elementary enough to be of value to the general scientific reader. The subject matter is based on the author's lectures, which are delivered to medical candidates in radiology. The history of radiation biology is discussed in the first chapter. Chapter 2 is a short review of general cytology. The scope of radiation biology is discussed in chapter 3, and the types of biological response to the action of penetrating rays are covered in chapter 4. The next three chapters deal specifically with irradiation of the skin and the alimentary canal, of the blood and circulatory system, and of the generative system. Chapter 8 deals with whole body irradiation and the use of atomic energy as a source of penetrating radiation. Chapter 9 discusses the application of radiology in cancer. The last chapter is devoted to theories concerning the actions of penetrating rays on living cells. The book contains 60 illustrations. The bibliography is arranged by chapters and includes only books of interest to the general scientific reader; those with strictly medical titles have been omitted. The effective style, which seems to simplify even the most difficult points in radiation biology, makes this book worth while for anyone who wishes to be informed on the subject.

Local Analgesia: Abdominal Surgery. By R. R. Macintosh, M.A., D.M., M.D., Nuffield Professor of Anæsthetics, University of Oxford, Oxford, England, and R. Bryce-Smith, M.A., B.M., B.Ch., First Assistant, Nuffield Department of Anæsthetics, University of Oxford. Cloth. $5. Pp. 94, with 88 illustrations by Miss M. McLarty. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; E. & S. Livingstone, Ltd., 16 & 17 Teviot Place, Edinburgh 1, 1953.

This small book illustrates how effectively attention can be drawn to a particular technique used in anesthesiology. The authors' apparent apology for the book is given in the preface: "If the reader does not share our view he will perhaps think it appropriate that this book should come from Oxford, the proverbial home of lost causes." This book is timely, for with the use of thiopental (Pentothal) sodium and curare local anesthesia is being abandoned when it would greatly increase the value of these agents. In addition to giving sound advice with regard to drugs, dosage, and concentration, the work covers briefly almost all the other pertinent information on the subject. Many illustrations are used, which allow condensation of the text. This is the best contribution that Oxford has made to the literature on anesthesia and it should be read carefully by all who are interested in anesthesia and in surgery.

Physical Examination on the Surgical Patient. By J. Englebert Dunphy, M.D., F.A.C.S., Associate Clinical Professor of Surgery, Harvard Medical School, Boston, and Thomas W. Botsford, M.D., F.A.C.S., Clinical Associate in Surgery, Harvard Medical School. Cloth. $7.50. Pp. 326, with 188 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

These authors have, as Francis D. Moore says in the foreword, "emphasized not only the detailed techniques of examination, but also the approach to the patient as an individual. It is in this wise that the student gradually develops that clinical acumen which later on will tell him so much about the patient, his disease, his educational and social status, his fears, his anxieties, and his adjustment to the medical environment in which he finds himself. It is this clinical sense which will lead the young doctor to think of his patient as a man away from home, not a hospital case."

This is not a book of surgical technique, but it does discuss adequately many techniques in surgery. Physical signs are interpreted in relation to the pathology and disordered physiology of the disease. The primary purpose of this volume is "to focus attention on methods of importance of eliciting physical signs in surgical conditions." It fills a real need in student teaching, for it is intended to provide the student with knowledge that will make him more competent in diagnosis of surgical disorders. There are many excellent illustrations. The subject matter is clearly presented, and the index is complete. This is a magnificent and useful volume.

Trichloroethylene Anæsthesia. By Gordon Ostlere, M.A., M.B., B.Chir., Deputy First Assistant, Nuffield Department of Anæsthetics, University of Oxford, Oxford, England. Cloth. $2.25. Pp. 83, with 5 illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; E. & S. Livingstone, Ltd., 16 & 17 Teviot Place, Edinburgh 1, 1953.

This small book on trichloroethylene contains five chapters dealing with history, general characteristics, pharmacology, anaesthesia, and analgesia and concludes with a brief summary and an adequate index. Each chapter is followed by an extensive list of references, which are the most valuable part of the book. Complications associated with the use of this drug are adequately presented. The format of the book is excellent. Any physician interested in trichloroethylene will find this brief, compact volume valuable for reference.

General Physiology. By Bradley T. Scheer, Associate Professor of Biology, University of Oregon, Eugene. Cloth. $7. Pp. 613, with 110 illustrations. John Wiley & Sons, Inc., 440 Fourth Avenue, New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C.2, 1953.

General physiology is necessarily an abstract subject, and the author of this book notes in a frank and interesting preface that this analysis of physiological phenomena in terms of fundamental concepts is to supplement physiological knowledge obtained in the laboratory. The five parts of the book are devoted to physicochemical foundations, chemical dynamics of life, energy transformations in cells and organisms (including bioelectricity, muscular movement, and radiations), the development of organisms, and integrative processes (especially nervous and humoral transmission).

The text is accurate, clear, and smoothly written. The smoothness is achieved in part by efficient handling of the 1,453 bibliographic references. These are in alphabetical order at the end of the book and are represented in the text only by small superscript numbers. Elimination of names and dates permits concentration on scientific ideas and will be appreciated by readers to whom the old familiar formula "In 1898 Bayliss showed that . . ." has become wearisome and distracting. The author has also put some of the necessary new abbreviations, like ATP (adenosine triphosphate) and RNA (ribonucleic acid), in the index. This book presents, in a scholarly manner, a wealth of carefully documented facts, and it deserves a place in every library of physiology.

Künstliche radioaktive Isotope in Physiologie, Diagnostik und Therapie. Bearbeitet von J. D. Abbatt et al. Redigiert von H. Schwiegk. Cloth. 136 marks. Pp. 842, with 294 illustrations. Springer-Verlag. Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

The first part of this excellent book gives a minute and comprehensive account of the physical, chemical, and biological facts underlying the rest of the work; this includes methods of measurement, treatment of biological materials, problems of dosimetry, and general biological effects. The second part, use of radioactive isotopes as tracers in physiology, pharmacology, and diagnosis, discusses individual chemical elements and applications to special problems in oncology, circulation, and endocrinology. The third part concerns therapy and covers local (including intracavitary) methods of administration, treatment of tumors, blood dyscrasias, and diseases of the thyroid.

There are some American and British contributors along with the German. Owing to the care of the authors, editor, and publisher, there is excellent integration of content and style, and there are no obvious errors in either the German or the English portions of the text. The book is authoritative and richly illustrated, and there is a good subject index. The alphabetized bibliographic references at the end of each chapter form an author index. This book is valuable to anyone who uses radioactive isotopes in the laboratory or in the clinic.

QUERIES AND MINOR NOTES

GAMMA GLOBULIN

To the Editor:—*I have read the plans for allocation of gamma globulin during the coming months and note that supplies are allocated for measles and infectious hepatitis. I would like to raise the question of further allocation for mumps in adult males and for prophylaxis of german measles (rubella) in early pregnancy. Although the efficacy of gamma globulin in these conditions is not well established, it should be available to the physician who wishes to use it, because of the well-known complications of these two diseases.*

Milton R. Aisenson, M.D., Kew Gardens Hills, N. Y.

Answer.—Evidence in support of the proposal to allocate gamma globulin for the prophylaxis of German measles in pregnant women exposed to the disease is suggestive but inconclusive; in the case of mumps, it is nonexistent. A study of 262 children in a closed institution experiencing an epidemic of rubella was reported by the Subcommittee on Gamma Globulin of the Medical Society of the County of New York (*New York Med.* 5:21 [Dec. 5] 1949). One hundred and thirty-three were injected with 6 cc. of gamma globulin and 129 retained as controls. In two of the former group, the disease developed within two days after injection and in six subsequently. In the same period, there were 22 cases among the controls. McLorinan (*M. J. Australia* 2:390 [Sept. 9] 1950) reported seven failures of prophylaxis among 520 pregnant women given 4 cc. of hyperimmune globulin within eight days of exposure. On the other hand, Korns (*J. Infect. Dis.* 90:183 [March-April] 1952) reported three trials, with the results respectively one apparently successful, one unsuccessful, and one equivocal. Bass (Advances in Internal Medicine, Chicago, Year Book Publishers, Inc., 1952, vol. 5), admitting the evidence for effectiveness is far from conclusive, nevertheless recommends giving 20 to 30 cc. as a prophylactic measure.

In the case of mumps, Gellis and associates (*Am. J. M. Sc.* 210:661-664 [Nov.] 1945) have presented some evidence to show that hyperimmune gamma globulin may be of some value in preventing the development of orchitis after the onset of parotitis, whereas normal gamma globulin was of no value. On the other hand, Enders and Janeway (Viral and Rickettsial Infections of Man, ed. 2, J. B. Lippincott Company, 1952, p. 519) have shown that doses of convalescent serum up to 200 cc. do not protect and that the antibody titers of such serum are relatively low.

In weighing the evidence for the use of gamma globulin in these conditions, it is important to distinguish between studies done with hyperimmune (convalescent) globulin and with globulin derived from large donor pools. Only the latter is available for allocation. In view of these circumstances and of the critically limited supply of the material, the Office of Defense Mobilization has of necessity limited allocation to those conditions in which it is of established prophylactic value.

CONTAMINANTS THAT MAY PROVE FATAL

To the Editor:—*What organisms will grow on whole blood at refrigerator temperature and are found occasionally as contaminants that produce serious and sometimes fatal illness?*

Victor Gregory, M.D., Portland, Ore.

Answer.—Organisms occasionally encountered as contaminants that will grow in banked refrigerated blood belong to several genera. The following organisms have been isolated from such a source: Micrococcus pyogenes aureus, Micrococcus pyogenes albus, Micrococcus citreus, alpha and beta hemolytic streptococci, Bacillus subtilis, Bacillus cereus, Bacillus mycoides, Pseudomonas aeruginosa, and species of Corynebacterium or Vibrio. Not all strains of these species can be expected to grow at low temperatures. Purposeful contamination of small quantities of citrated blood with dust or skin scrapings followed by storage of the blood in the refrigerator will yield the most satisfactory source of such organisms. All of these organisms are capable of producing serious illness if introduced intravenously in sufficient quantities with banked blood. Fatal and near fatal results from contamination with most of those listed have been observed. Further information may be obtained from the references below.

BASEBALL "PITCHER'S ELBOW"

To the Editor:—*A 29-year-old baseball pitcher complains of chronic soreness of his right elbow ("pitcher's elbow"). The disability limits his playing time to about three innings. Can you give me any advice as to treatment and prognosis? Roentgenograms show no evidence of calcification.*

N. L. Masson, M.D., New York.

Answer.—"Pitcher's elbow" is usually associated with an incomplete rupture or tear of the tendinous attachments of either the extensor or the flexor group overlying its corresponding humeral epicondyle. In the beginning, rest and active exercise (pitching to the point of tolerance) should be permitted. Applications of external heat (infrared rays or diathermy), with gentle massage over the tender areas, may be given. Injection of procaine hydrochloride, 3 cc. of a 2% solution, into these areas may be done on alternate days. Graduated passive exercises to break up adhesions, either by abduction or adduction of the extended elbow with the wrist in supination, may be tried. Surgical treatment may be necessary as a last resort. This would consist of division and dissection of the attachments of the common extensor or flexor tendon group from the corresponding humeral epicondyle, with removal of any thickened or hypertrophied synovium or bursa from the radiohumeral joint. The prognosis depends on the duration and severity of the condition.

FRIEDREICH'S ATAXIA

To the Editor:—*A man, aged 34, has had hereditary cerebral ataxia for six years. Several cousins, aunts, and uncles have died from the disease, and his father has it. I have been unable to find help for him either through the literature or from consultants. Can you offer any suggestions?*

M.D., Maine.

Answer.—Presumably Friedreich's ataxia is meant, as there are no forms of "hereditary cerebal ataxia." Unfortunately, there is no known treatment of value for this condition, and the disease is likely to have a progressive course. All hereditary diseases show a tendency at times to become arrested spontaneously, and that possibility must always be held out to such patients as a hope.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

PRINCIPLES AND PRACTICE OF PROGNOSIS, WITH PARTICULAR REFERENCE TO HEART DISEASE

BILLINGS LECTURE

Paul D. White, M.D., Boston

Although the importance of prognosis (preknowledge or forecasting) in medicine was clearly appreciated by Hippocrates, it has progressed very little and very slowly through the many centuries in contrast to the scientific development of etiology, pathology, diagnosis, and treatment. In the Dark and Middle Ages it drifted almost wholly into superstition. It still remains a stepchild in medical advance partly because it is a difficult subject and partly because, for some reason or other, it has rarely been studied scientifically. The few sentences devoted to it in the account of almost any disease or condition in almost all textbooks and papers are little more than a sop to the conscience. In cases of cardiovascular disease, the statement of prognosis often ends with the word "guarded," largely to play safe. Granted that we can not foretell the future with any certainty, I feel sure, nevertheless, that we can do better than we have in the past, or are doing now, by approaching the subject more scientifically and seriously. We have more facts and knowledge on which to base our prognoses than we utilize; we should call more than we do on the laws of chance in both our written opinions of prognosis of any disease and our discussion of the prognosis of any individual case with the patient himself, with his family, or with fellow physicians.

Here and there, however, in the past there have been physicians who have pointed to the importance of developing a more scientific attitude toward prognosis. For example, James Mackenzie, in the third edition of his book entitled "Diseases of the Heart" published in 1913,[1] wrote as follows in chapter 45 entitled "Prognosis": "I am rather afraid that our profession as a body does not recognize sufficiently its responsibility in regard to prognosis. When an individual submits himself for an opinion he does so with such implicit confidence that the verdict given may alter the whole tenor of his life. . . . A serious responsibility is thrown upon every practitioner at times in advising upon certain questions. 'Should a man give up his business?' This is a question on which advice is constantly sought and whether the individual be a statesman or a laborer, the greatest care is necessary in formulating an answer. If a practitioner seeks for guidance in the textbooks he finds merely general views which he cannot apply to the individual case."

The greatest difficulty in prognosis lies in its complication. There are more factors to be taken into consideration, especially in cardiovascular prognosis, than there are in either diagnosis or treatment. These factors are never just the same in any two cases, and so the prognoses listed in books or papers under the various kinds of heart disease are necessarily very rough estimates; the averages actually apply to very few cases. The difficulties in determining the outcome are illustrated in the discussions of prognosis in the sections on vascular hypertension, congenital heart disease, subacute bacterial endocarditis, and other common forms of heart disease in Cecil and Loeb's "Textbook of Medicine." [2] In the fourth edition of "Heart Disease" published in 1951,[3] I combined "prognosis" with "course" because of the difficulty of writing adequately about prognosis as an isolated subject.

There are many factors that combine to form the basis for cardiovascular prognosis in any given case. Thereon rest the foundations of the principles and practice of prognosis that should rightly become, with time, a science rather than an art. I will present 10 factors, although another might well be added representing chance and unexpected circumstances beyond our control or even beyond our knowledge. Often, of course, the experienced physician does, in the course of his career, acquire some considerable skill in prognosis, but this is often hit or miss and without conscious analysis of the separate factors that I will present.

HEREDITY

The first very basic factor in prognosis is heredity. There is no question but that, other things being equal, the person with long-lived ancestors who were resistant

to disease or who possessed the ability to withstand disease, whether it involved the heart or affected other body tissues, is more likely to survive a long time with some disorder or to recover from some very serious illness than is another person whose parents, grandparents, or siblings have succumbed early to some disease or have been more seriously disabled by it than would be expected. The more members of the family, immediate or in recent generations, of whom this is true the worse for the patient under consideration. The prognosis in the case of a 40-year-old man with coronary thrombosis is necessarily worse if both parents died from the same disease when they were in their forties or fifties. And, of course, the disease itself is, in the first place, much more likely to strike such a man in youth or middle age than it is a man whose parents remained healthy until advanced old age. The hazard is more than doubled when both parents were so affected at an early age than when the father alone was affected. The maternal inheritance is thought to be more potent than the paternal; perhaps this is so because it is relatively rare for a woman under 50 to have serious coronary atherosclerosis. When she does, it is much more significant than in a man. More studies of this relative sex responsibility are, however, needed for fuller appraisal of prognosis.

In practice, therefore, it is of great importance in the majority of cases for the physician to inquire specifically about the ages and causes of death or important illnesses in parents and siblings and even, on occasion, in grandparents, uncles, aunts, and children. This is frequently not done because of haste or carelessness, but its value should make it a routine procedure, at least in the case of cardiovascular disease.

An unfavorable family history should not depress any given patient; other more favorable factors can come into play to counteract it, including the almost certain new knowledge about the etiology, pathogenesis, and prevention of certain conditions, such as hypertension and coronary atherosclerosis, that is destined to be ours in the future. The application of this new knowledge will doubtless save or prolong many lives that are now seriously threatened and eventually protect at least in part from such diseases young persons who are likely candidates.

AGE AND SEX

Another factor that is related in particular to the patient is his age. Other things being equal, the older the patient after the period of infancy, the worse the prognosis. It must be realized, however, that chronological age is not the same as physical age. This fact must not only be recognized but be acted on in individual cases.

A factor also related to the person himself is his sex. Again, other things being equal, men are more vulnerable and have an earlier and higher mortality than women, particularly from cardiovascular disease. Of my own patients under the age of 50 with serious hypertension and hypertensive heart disease, three-fourths were men. It is, of course, common knowledge that coronary heart disease is, in particular, one of middle-aged men, and in such cases the prognosis, in my experience, has been somewhat worse than in women. Coronary thrombosis affects more than 20 times as many men as women under the age of 40 and about 5 times as many between 40 and 50. In the fifties, the ratio is about two to one, and after 60 the proportion is nearer one to one. Whether or not we may be able to alter this poor prognosis in men with time and trial, it is too early to say. It has been suggested that new therapy with hormones, perhaps combining the favorable effect of estrogen with the favorable effect of androgen, may eventually prove to be helpful. This is, however, still wholly a matter of the future.

TYPE OF DISEASE

The type of heart disease is, of course, of paramount importance, but happily in some types the picture has changed since a generation ago. At that time two kinds in particular had very bad prognoses. The worst was, of course, subacute bacterial endocarditis; it was about 99.9% fatal prior to 1944, but now it is better than 80% curable in efficient hands. It should be better than that eventually. The change that has come in our experience with subacute bacterial endocarditis can justifiably encourage us about other diseases that still carry bad prognoses.

The other serious type of cardiovascular disease that used to plague us was syphilitic aortitis. By the time an aortic aneurysm was large enough to be diagnosed or aortic regurgitation with an enlarging heart was found, the prognosis was already bad for any long survival; there were but a few months to a few years at most ahead. Now, of course, penicillin can check the progress of such conditions, except when far advanced, and cardiovascular syphilis itself is rapidly becoming history both because of the reduction of prevalence of the original lesion and because of its curability in either primary or secondary phases.

Congenital defects of the heart and the aorta still remain a baffling problem in many instances, with early death in infancy of some of the more intractable lesions. The horizon has greatly brightened, however, for thousands of persons with defects that now can be cured, in particular those with patency of the ductus arteriosus, uncomplicated pulmonary valve stenosis, or coarctation of the aorta, and for many others who can be helped although not cured, in particular the blue babies with the tetralogy of Fallot. Except for rare combinations of anomalies of other sorts, a large number of persons with atrial and ventricular septal defects remain to be helped. The former defects are already being operated on successfully, and it should not be too long before the latter also are helped by the skill of the cardiac surgery of the day.

The prognosis of rheumatic heart disease varies tremendously according to the severity of the initial myocardial involvement, the amount of valvular deformity, and the hazard of recurrent rheumatic activity. There has been, however, a considerable amelioration of these three factors, largely because of the prophylactic use of penicillin and, in fulminating cases, the apparent lifesaving effect of the hormones (cortisone and corticotropin), the successful reapplication of plastic surgery of the badly stenosed mitral valve, and the more scientific appraisal of the physical fitness of the patients. Now rheumatic scarring of the aortic valve is also being attacked surgically, and it seems quite conceivable that within a few years the damaged aortic valve itself can be improved or that a plastic valve can be introduced to correct the leak in regurgitation. It behooves all of us who have been following congenital or rheumatic heart cripples for years to see them again or send them to others for a new appraisal since a number of them can certainly be helped by present day surgery.

Another kind of heart disease that, although not common a generation ago, was often serious with bad prognosis is the thyrotoxic heart. Atrial fibrillation, generalized enlargement, and congestive failure frequently threatened life. Then came early surgery with subtotal thyroidectomy that, though often hazardous, did save lives. The prognosis today of thyrotoxic heart disease has improved so much that it is a very rare case indeed that cannot be helped to live at least a few years longer, not so much because of the advance in surgical therapy that can be applied but because of current medical treatment of the thyrotoxicosis itself added to ordinary measures for the control of the arrhythmia and congestive failure that are characteristic of advanced cases. Much more important, however, than this treatment of thyrotoxic heart disease is the remarkable reduction in prevalence of thyrotoxicosis as the result of its early recognition and cure, whether surgical or medical, before the heart becomes seriously involved.

In comparison to the kinds of heart disease presented above, in which the prognosis has been considerably improved of late years, there remain three types that continue to challenge us and for which we can, as yet, do little to better the prognosis. The first of these, although not very common, is cor pulmonale, both the chronic and the acute types. Advances have been made in the reduction of the number of cases as the result of protection from industrial dust disease, in particular silicosis, decrease in chronic and recurrent pulmonary infections, and more effective control of pulmonary embolism. By the time, however, that the heart is seriously affected, either acutely or chronically, with dilatation and failure of the right ventricle, the prognosis is very grave and life hangs in the balance. In the acute cases, there is as much, if not more, of a threat from shock or another pulmonary embolus as from the cardiac status itself. In the chronic cases, the underlying pulmonary disease or infection superimposed theron is likely to terminate life.

A grimmer problem is that of hypertensive cardiovascular disease because of its great prevalence and our failure to discover adequate specific therapy. There are many mild cases with good prognoses for many years, but, even of these, some become malignant; we cannot always prophesy which these will be. Even mild to moderate hypertension when added to other types of heart disease, especially the coronary disease, can be the "last straw to break the camel's back." It is in the study of patients with hypertension in particular that we need to gather together all known factors, such as heredity, on which to base a reasonable individual prognosis, since this condition almost more than any other allows a very great range of longevity. It is also of interest to try to determine when possible where the greatest threat lies, on the heart, on the cerebral circulation, or on the kidneys. It is all very well to state that about 60% of the patients with hypertension die cardiac deaths, that 20% have fatal cerebral vascular accidents, that 10% die of renal involvement, and that the remaining 10% die from other intercurrent disease. It is sometimes possible, however, to particularize in estimating the prognosis. For example, a very high diastolic pressure in a young or middle-aged man is an immediate threat to the heart especially; beginning abnormalities of urine and renal function point to serious kidney disease; and so-called hypertensive encephalopathy, especially with "little strokes," favors termination of life by a cerebral vascular accident.

Finally, the most difficult problem in cardiac prognosis, and one that concerns coronary heart disease, is angina pectoris. We have learned much about the prognosis of angina pectoris and myocardial infarction during the last 25 years, more than in all the centuries before and more than about almost any other aspect of the disease, such as pathogenesis and treatment; we have much more to learn than we know now, however. Even with what we have learned, we still feel that it is wise to "guard" the prognosis in almost every case. I believe, however, that if we analyze conscientiously all the other basic factors we are entitled to do more than to say of every patient with coronary heart disease that "God alone knows" about his future. It is here in a disease that is so prevalent and often so serious that we need most to apply what we already know or can learn about a patient both in our prognosis and in the limited treatment that we can recommend. Many patients with angina pectoris, whether mild on unusual effort or severe at rest, improve spontaneously or even recover completely in the course of weeks, months, or at most a few years because of the development of an adequate collateral coronary circulation. Some such patients are perfectly well 10 to 20 or more years after the first attack of angina pectoris, even though the electrocardiograms continue to be abnormal all the rest of the patient's life. On the other hand, some patients are so sick that they die of the very first attack or of some complication. What I have said about effort angina pectoris and angina pectoris decubitus is also true of coronary thrombosis with or without infarction; in the case of an infarct, a perfectly firm, well-healed scar may cause no trouble for the remainder of a long life.

In any case of coronary heart disease, no matter what its symptomatology, it is essential to appraise all the other factors in order to try to come to a reasonable conclusion about the prognosis. No two persons are exactly alike in these factors, and so we must particularize every case. At the present time, we are prone to say that the prognosis of coronary heart disease permits a range of one minute or less of life at the onset of the very first attack of angina pectoris to over 30 years for rare persons and that we have found that the average duration of life in several hundred cases of angina pectoris has been a little over 10 years, but that isn't nearly good enough. I'm sure that with the careful appraisal of all the factors, from that already referred to above as heredity to the last that I shall mention, namely the physician's own attitude, we can do much better in the future. We may eventually be able by the laws of chance to be reasonably successful in a given case, but that case must be individually and carefully appraised.

There are less common kinds of heart disease that should be referred to very briefly. As a rule their prognoses are oftener dependent on involvement of other parts of the body by the same factors than on that of the heart, as for example malignant tumors, trauma, certain infections and infestations, collagen and blood diseases, and malnutrition with avitaminosis. We can say little about the rare case of extensive myocardial disease of unknown cause except that the prognosis is usually bad by the time such a diagnosis is made, and survival is for months, or a few years at best.

DEGREE OF DISEASE

Of prognostic importance at least equal to the kind of heart disease is the degree or severity of that disease. Although this would seem rather obvious and is actually generally taken into account by the physician in every case, it is not adequately expressed in books or other writing. It is perfectly true that there may be a "touch" of coronary heart disease, of rheumatic heart disease, or of hypertension or only very slight coarctation of the aorta or of pulmonary stenosis just as there may be a fulminating or extreme degree of any of these conditions. And there may be in the same case a slight degree of one kind of heart disease and a high degree of another. For example, I have seen serious myocardial infarction in a patient with a trivial old rheumatic mitral valve lesion; in such a case one should base prognosis on the severe lesion and not alter it much on the finding of the lesser lesion. It has been said that on occasion one abnormality may compensate somewhat for another, hypertension for coronary insufficiency or for rheumatic mitral stenosis, but I have not found it so. In my experience the various lesions are additive in their prognostic significance, except rarely in referring to a particular state such as systemic venous congestion caused by chronic constrictive pericarditis or tricuspid stenosis added to mitral stenosis. In the latter condition if there is tricuspid stenosis as well as mitral stenosis, life is shortened but there may be a longer period, years sometimes, of systemic congestion due to the mechanical effect of the tricuspid stenosis (or of constrictive pericarditis) than when right ventricular myocardial failure is responsible, caused as it commonly is by mitral stenosis or by left ventricular failure secondary to aortic valve disease, hypertension, or myocardial infarction. At one time, the outcome of subacute bacterial endocarditis was all or none. It was uniformly fatal so that it didn't much matter whether it was only mild when first discovered. Now that it is usually curable, its extent does matter, although there remain exceptions to that statement.

One of the most important clues to help in estimating the degree of heart disease is the size of the heart. In general, the larger the heart the worse the prognosis.

STAGE OF DISEASE

Generally speaking, the earlier the stage the less severe the condition, as in myocardial failure, and the better the immediate prognosis with adequate treatment. Atrial fibrillation similarly is more amenable to treatment with restoration of normal rhythm if recognized at or soon after its onset. Sometimes this statement doesn't hold, however, as in the case of massive myocardial infarction, which is perhaps the greatest threat to life during the very first hour or two when it may produce serious shock. Even here, however, the earlier adequate treatment can be applied the better the prognosis.

TREATMENT

And again this leads us naturally to the seventh factor, namely the adequacy of the treatment. When antibiotic therapy was first introduced for subacute bacterial endocarditis, there continued to be a high mortality (though less than before) because there was not enough penicillin for a good many of the cases. As soon as enough penicillin or other antibiotics were available and were given early and adequately enough, the mortality steadily dropped to its present figure of something less than 20%. Congestive heart failure, which was not very well treated in my medical student and hospital intern days, is now very much better handled with fuller application of satisfactory digitalis usage, the introduction of the low sodium diet, and the wide employment of the mercurial diuretics. Patients sometimes used to die water-logged only a few months after the first evidence of myocardial weakness and failure; now their lives are not infrequently prolonged for several years and the edema controlled, at least in large part. Today such patients still die, but they are no longer water-logged. More often they die from complications, such as pulmonary embolism, than from the heart failure per se. Even the most ignorant physician is supplied with therapeutic tools that permit him to prolong lives that would have been lost a generation or two ago.

MEDICAL KNOWLEDGE

And this in turn leads us to the eighth factor that influences prognosis. That factor is the amazing annual increase of medical knowledge resulting largely from research. Right around the corner there may be a cure, or at least some improvement of a current therapeutic measure, that may radically alter the prognosis. One of the most exciting examples of this possibility is that of congenital cardiovascular disease. Septal defects of the heart are conditions that may fit here. Until very lately only sporadic efforts were made to correct them, but quite recently cardiac surgeons have devised techniques that enable them to close openings in the atrial septum. It seems quite likely that within the relatively near future ventricular defects may also be repaired, especially if the blood can be temporarily diverted by an artificial pump. Aortic valve surgery is also in its infancy, and before many years we may be able to prognose about cases of severe aortic regurgitation or marked aortic stenosis more favorably. Who would have dreamed 10 years ago that surgical cure of coarctation of the aorta would be almost commonplace? Even serious and intractable angina pectoris is already yielding, at least for considerable periods of time, to the radical medical thyroidectomy effected by the oral administration of irradiated iodine.

PATIENT COOPERATION

One of the most vital of all the factors in prognosis is the cooperation of the patient himself. He should have enough understanding of his heart disease and of the treatment, including even the minute details thereof, and enough confidence in his physician to follow his recommendations wholeheartedly. The difference between life and death may easily depend on this factor. That is why it is so essential for the physician to establish at the very beginning a good relationship and to take time to explain as fully as necessary what is wrong and what should be done, without going into tedious detail or recounting all the bad complications that could develop. An hour spent thus may save weeks and months of miserable apprehension and unhappy rebellion. I cannot overemphasize the value of this relatively simple measure that can so vitally affect both prognosis and treatment. Also it saves the time and energy of the patient who, not learning enough from his physician, surreptiously or even openly resorts to medical or quack literature. If inadequately informed, the patient may "shop around" until he finds a physician or clinic to give him advice to suit his fancy.

ATTITUDE

The last of this series of factors behind cardiovascular prognosis, and treatment too, is the attitude of all concerned including the physician, the patient, his family and friends, and even on occasion the community too. Twenty-one years ago I presented a paper entitled "Optimism in the Treatment of Cardiovascular Disease" based on a group of patients who had gotten along better than had been expected. This experience added still more to my optimism, and this was reflected in the attitude of my patients. Yet optimism can be overdone. It should not be allowed when there is no possible justification for it. On occasion, it can give rise, when unwisely used, to overconfidence and carelessness on the part of both physician and patient and lead to unfortunate results. The old adage of "while there is life, there is hope" proves true often enough even in the sickest patients to justify its use without any overconfidence. The patient's interest in living may be supported by the attitude of those about him, and this may be the narrow margin needed for survival. It is, to be sure, difficult to weigh this factor of attitude, but from experience we know that it counts and so we should use it to the best of our own ability and try likewise to persuade the patient and those about him to make the most of it.

CONCLUSION

What remains to be done now is assessment of the relative values of the various factors that I have mentioned, but this an extremely difficult task to perform; in fact, in the present state of our knowledge, or of our ignorance, it is practically impossible. Every case must be appraised individually; in none are all of the factors of exactly the same value. Yet a start can be made now, and eventually this art can become a science. Each factor might be graded as favorable or unfavorable, then the various factors might be given relative values, and finally, a total estimate figured, based on the laws of probability, with still an additional percentage of something unforeseen. This obviously is too complicated at present and so I will not belabor the point. I do believe, however, that we can do better than we are doing now about the prognosis of heart disease.

264 Beacon St. (16).

ROLE OF PHYSICIAN IN PREVENTION OF MUSCULOSKELETAL DEFORMITY AFTER POLIOMYELITIS

Robert L. Bennett, M.D., Warm Springs, Ga.

Even as this report is being made, everyone is hoping that a vaccine will be developed that will prove that acute anterior poliomyelitis need no longer be feared. Although this is no idle dream but a reasonable expectation, it does not alter the demands for care arising from the epidemics of this year, of many years past, and, perhaps, of a few years to come. Because of the nature of this disease, its prevention, but not its cure, can be reasonably expected. To those physicians who treat the after-effects of poliomyelitis, this realization of their limitations is not new, and they are all keenly aware that despite their greatest efforts, their success in preventing deformity and restoring some measure of physical independence must soon seem negligible when compared with the proof that prevention of the disease itself is assured.

Since it is so easy to blame the limitations on the nature of the disease itself, it becomes all the more necessary to assess the physician's possibilities and thereby define his responsibilities. Admittedly, the after-effects of poliomyelitis are difficult to care for, but there seems little excuse for the gross negligence and disregard of principles of care so commonly seen. Because no two patients are alike, the physician can blame the products of his inadequacy on the underlying disease, the patient's personality, the family's lack of cooperation, in fact everything but his own failure to provide the necessary essentials of care. At the very least, the physician who accepts the responsibility for the care of the patient with poliomyelitis must have the training and facilities to prevent or minimize, insofar as is humanly possible, the musculoskeletal deformities so characteristic of the after-effects of that disease.

Even though adequate facilities for intensive muscle reeducation are not always available, the control of deformities must be accepted as the physician's respon-

---

Medical Director and Director of Physical Medicine and Rehabilitation, Georgia Warm Springs Foundation.

Read before the joint meeting of the Section on Pediatrics, the Section on Physical Medicine and Rehabilitation, and the Section on Preventive and Industrial Medicine and Pubic Health at the 102nd Annual Session of the American Medical Association, New York, June 4, 1953.

sibility. Before this responsibility can be fully appreciated the following facts must be recognized: 1. The causes of deformities can be determined before the deformity is evident and in most cases can be adequately controlled if discovered and treated early. 2. The presence of even mild deformities can severely limit the possibilities of recovery through muscle reeducation and functional training. 3. A deformity never exists alone, but rather one deformity causes another and can be expected to cause a chain of disabilities, perhaps far removed from the site of the original one. 4. Deformities must be prevented, because they rarely can be corrected by conservative measures once they have developed. These are proved facts, not fancies, and put the responsibility squarely up to the physician who accepts the care of these patients.

Unfortunately, the development of the usual musculoskeletal deformity is slow and insidious. At its beginning it does not cause specific pain, swelling, fever, unconsciousness, or any of the symptoms or signs commonly associated with impending disaster. Many physicians who would consider it a disgrace to permit an appendix that is acutely infected to rupture while a patient is under their care apparently have no such feeling about development of deformities in their patient with poliomyelitis. Too frequently the physician is incapable of examining the musculoskeletal system. By the time he finally realizes that all is not well, deformities are far advanced and largely uncorrectable.

It can be said that, when a deformity is easily recognized, it is then too late to do much about it. Simply stated, the deformities that are included in this report may be defined as distortions of bodily alinement and/or mobility due to structural changes in the tissues that make up the musculoskeletal system. If atrophy due to denervation and the depression of bone growth that probably has the same basis are excluded, it can be stated that all other deformities result from nothing more mysterious than persistent, faulty position. It must be realized that, if any portion of the body is repeatedly held or forced into a faulty position, irreversible changes in those tissues making up that bodily segment must eventually take place. Thus, deformities can occur during periods of rest or activity. They will develop in direct proportion to the intrinsic strength of the tissues involved, the force of the stresses applied to these tissues, and the period of time these stresses are applied.

The causes for faulty positions are many. Muscle weakness, or imbalance of muscle strength, and changes in the intrinsic tone of supportive structures are usually the underlying factors in the development of all deformities. Certainly these may be complicated by the presence of pain and spasm. Even these factors would not cause significant deformity if not aggravated by the controllable factors of poor nursing techniques, inadequate splints and braces, haphazard patterns of movement, obesity, irresponsible weight bearing, and overactivity. There are many methods of preventing deformities, ranging from the use of pillows and sandbags grossly supporting the body to plaster casts completely enclosing the involved segments. Each method has its advantages and disadvantages. Pillows and sandbags are immediately available, are easily rearranged, and, if used expertly, provide the comfortable support so necessary during the acute and very early convalescent phases. But pillows and sandbags are of little or no value when activity is increased. Plaster casts can be readily applied and will rigidly hold any position the physician decides is necessary, but closed casts preclude the maintenance of joint mobility and the early graded activity that constitutes the basis of modern treatment. Neither of these methods, therefore, have more than temporary value, and they constitute a real threat to the patient's future if used too long. Optimum recovery demands a careful balance of activity and inactivity during convalescence. This usually requires at least the temporary use of supportive apparatus. When externally applied support is necessary, it must be easily applied and just as easily removed. It must adequately support the weakened segments and, if at all possible, permit and even assist safe patterns of movement. Unfortunately, such apparatus is not always readily available. Many brace makers have been slow to accept their responsibility as a member of a team that must function not only expertly but quickly. Deformities, particularly in the hands and feet, develop rapidly and might well be irreversible if the splints are not delivered until weeks or even months after they are ordered. The medical profession would not tolerate such irresponsibility from a druggist. On the other hand, if all physicans who treat patients with poliomyelitis were capable of determining the type of apparatus necessary, capable of writing specific prescriptions to the brace maker, and then intelligently checking the final fitting, the brace makers, I feel sure, would do their part.

Too frequently, a brace maker is blamed for his inability to make a comfortable and well-fitting hand splint, corset, or leg brace when the real reason is that the physician failed to see the need for such apparatus until after deformities occurred. Structural deformities of the hand and wrist, back, knees, and feet simply cannot be fitted with effective apparatus regardless of the skill and responsibility of the brace maker. It must also be realized that children grow, both children and adults change weight, and apparatus wears out. The perfectly constructed brace, corset, or shoe may be more dangerous than no support at all if the child grows out of it or it becomes distorted with use.

Perhaps too much emphasis has been placed on the use of apparatus in preventing deformity. It must be realized that the prevention of musculoskeletal deformities can never be accomplished through the use of apparatus alone. Recovery and resumption of activity go hand in hand. No brace, corset, or splint, regardless of strength and perfection of design, can possibly completely protect the patient against deformities arising from haphazard patterns of movement and overactivity, particularly in weight bearing positions. Obviously the physician must be trained and experienced in kinesiology so that he can recognize faulty positions and movements that must in time cause deformity. During convalescence only those activities that can be done coordinately and safely are permitted. In the chronic stage, functional activity may demand the use of abnormal patterns, but activity that would endanger future structural alinement must never be permitted. The physician should be constantly looking ahead to be sure activities permitted will not bring about deformity later.

When spotty paralysis so typical of poliomyelitis results, the remaining muscle strength may frequently have little value from a functional standpoint but may act as a severe deforming factor by its unopposed action. Muscle imbalance about the foot and hand commonly cause deformities in this manner. This requires careful evaluation by the physiatrist and orthopedic surgeon. If balance through muscle reeducation is not thought possible, then the deforming action should be eliminated by tenotomy. If possible, the insertion of the tendon should be transplanted to another position where use can be made of the strength of the muscle without its deforming action.

Even if an extremity is extensively paralyzed, it should be kept mobile and in good alinement. The use of assistive and adaptive apparatus including externally applied prosthetic appliances makes it possible to restore some degree of usefulnesss even to completely flail extremities. All too frequently, we find that such apparatus cannot be used because limitation of motion and structural distortion of the extremity has been permitted to occur. This is particularly true in involvement of the upper extremities where contractures make it impossible to apply "feeders" and other adaptive apparatus. Amazing improvement in functional capacity of an extremity with spotty paralysis is often possible through orthopedic surgery. Again too frequently, the extremity is neglected because "surgery will be done later." When the time for surgery finally arrives, deformities have developed and the surgeon is faced with an impossible problem.

Some of the most tragic examples of faulty positioning are seen in patients who were confined to respirators during early convalescence. The fact that a patient was confined to a respirator is no excuse for the severe contractures so commonly seen about the thumb, fingers, wrist, forearm, and elbow. The early and intelligent use of hand splints and gentle mobilization will easily minimize these deformities of disuse and persistent faulty position and will in no way interfere with the more dramatic lifesaving procedures. Again and again we have seen patients whose life was saved by the skilful use of respiratory aids only to find when they were finally weaned away from these aids that irreversible deformities of bodily segments had occurred. Even in the most critical and drawn-out respiratory problems, these deformities could have beep kept under control.

While there should be no compromise with normal skeletal alinement, the degree to which bodily segments are mobilized should be specifically determined in each individual case. If persistent contracture of tissues exists, it is wise to assume that underlying muscle weakness also exists. When significant weakness exists, "fortunate" or planned tightness may be necessary to prevent structural deformity and support necessary activity. Irresponsible stretching of the weak back might permit scoliosis to develop, which a little tightness would have prevented. Irresponsible stretching of the triceps surae might permit a severe calcaneous deformity to occur. Planned tightness would have safely anchored the os calcis and prevented its forward migration. A good rule to follow is that no structures should be stretched unless there is accurate knowledge of the underlying strength and the possibilities for deformity if mobility is accomplished.

SUMMARY

The prevention of structural deformities of the musculoskeletal system following poliomyelitis must be accepted as the physician's responsibility. Not all deformities can be completely prevented, but they can be kept within reasonable limits by known methods. No physician should assume the care of patients with the after-effects of acute anterior poliomyelitis unless he has (1) an understanding of the pathogenesis of musculoskeletal deformities, (2) knowledge of the relative importance of the various deformities and their relationship to each other, (3) training in kinesiology with the ability to recognize normal and abnormal static positions and movement patterns, and (4) the tools available to care for the factors that result in deformity.

Tumor Metastases.—The invasive properties of leukocytes and macrophages depend on their being isolated single cells *and on their highly developed ameboid motility*. That cancer cells also possess ameboid motility was reported as long ago as 1863 by Virchow and has been demonstrated in tissue culture by many workers in recent times. These tissue culture studies have shown beyond all doubt that tumor cells in general are ameboid, whether they are of mesodermal or epithelial origin.

Neoplastic epithelial cells from carcinomas of man and of laboratory animals have been photographed with a moving picture camera and their rates of speed determined. Cells from breast cancers, for example, moved at an average of 0.7 μ/min., with a maximum rate of 2.4 μ/min. Cells from a carcinoma of the kidney attained a maximum rate of 4.4 μ/min., while some cells from a mouse fibrosarcoma traveled at 6.2 μ/min. Of additional interest is the observation that even tiny clusters of three to five epithelial cells from a rabbit carcinoma progressed as an ameboid unit. It was also demonstrated that the cells of benign epithelial tumors and even nonneoplastic glandular epithelial cells (from cystic disease of the breast) may be motile in tissue culture, provided that these cells are first forcibly detached from their companion cells. It appears probable, then, that the local invasiveness of cancer cells depends upon their ability to progress by ameboid movement.

Why, then, do not the cells of benign tumors or the cellular components of the various organs also invade, since they too, at least in some instances, are capable of ameboid *motility*? There is evidence to indicate that the cells of normal tissues and also the cells of benign tumors are so firmly attached to one another that they are unable to escape. In contrast, the cells of malignant tumors are often found in the body free from the parent tumor.

The reason that the cancer cells become free is their greatly reduced adhesiveness. Micromanipulation studies have shown that the *magnitude of force required to separate* a pair of normal squamous epithelial cells from each other is much greater than the force required to separate cancerous squamo cells.—Dale Rex Coman, Mechanisms Responsible for t Origin and Distribution of Blood-Borne Tumor Metastase A Review, *Cancer Research*, June, 1953.

PRIVATE BEDS IN MEDICAL TEACHING

S. Howard Armstrong Jr.; M.D., Chicago

Teaching hospitals face today the large-scale use of private beds in their programs. The pressure is economic and unavoidable. Twenty years ago a public ward bed cost the patient $4 a day and cost the hospital not much more. Many a privately endowed teaching center had over 200 public ward beds divided among the teaching services. Today a ward bed costs the hospital between $15 and $20 a day. If the endowed hospital assumes the cost of as much as half the patient's bill, 200 teaching ward beds cost the hospital well over $600,000 a year—the interest on a 13 million dollar endowment. Most hospitals do not have such financial resources. The few that have, because of research and other commitments, do not want to expend all their funds on ward beds. With the growth of private hospitalization insurance, they are finding that they do not have to.

More and more insured patients demand private medical care. They enter the ward bed from the private physician's office, and they return to the office for follow-up. Hospitals that continue "free dispensaries" find little room to hospitalize their sick under the same roof and the care of the house staff. A dispensary without ward beds has no educational role. It can no longer provide vital continuity of patient observation.

With the shift to greater use of private beds, the practicing physician again resumes his ancient role in medical education. The patients are his, not those of his service chief, of the educational director, or of the medical school department head. The educational result is directly determined by his teaching skills, by his philosophy as to proper relations of old and young in medicine, and by his wisdom in appraising his freedom to act independently under pressures. The full-time staff member, the professional educator, at best can only help.

Therefore, this report is prepared for the practicing physician who wants background information on modern processes and standards of clinical education to strengthen teaching in his own hospital. It is not intended to provide the complete background. Taken as such, it will surely fail, for it represents a first and partial study. It poses many questions whose answers I *do not know.* It is based on about five years' experience in a predominantly private bed teaching hospital, in which I was a department head, more than five years of teaching at predominantly public ward hospitals, and many periods of observation of various types of hospitals over the country. In many such institutions the problems are being given vigorous thought and action. In the subsequent discussion some arbitrarily selected centers are cited, not as having uniformly workable solutions but as a profitable starting point for inquiry and visit. Many others that are not cited are as important in their contributions.

THE PROBLEMS

"Private beds in teaching" has been the subject of many a discussion at many a recent meeting of medical educators. Sometimes it is presented as a comparatively easy shift in patient material, but this is not always the case. True, a few hospitals, through concerted effort on the part of the attending staff, have successfully made the shift. They compete successfully for a high caliber house staff in this era of large discrepancies between number of positions and number of candidates. Other hospitals, sometimes as rich in facilities and in a respected senior staff, have not been so successful, despite elaborate printed programs, rising stipends, and full-time department heads.

Before the economic impact of World War II, the public wards and the dispensaries were the usual domain of clinical teachers. When chosen for his ability in and love of teaching, the ward clinician has always held high honor in his hospital regardless of the size or make-up of his private practice. With the exception of a very few centers, medical students were rarely assigned to private pavilions or semiprivate wards. When they were, they were usually paid an extern stipend as a recompense for lack of educational function.

The old hierarchical distinction between the private and ward house staff has been familiar in many a hospital dining room. Competition for the ward jobs was intense. The happy winners began by working 18 hours a day for board, room, and laundry. The private jobs in the same hospital often were held by men waiting, and saving, for a ward opportunity.

By and large, the public wards of our teaching hospitals have set a very high educational standard (though those indifferently staffed have sometimes fallen far below the few old-time private services that took teaching as their business). In my own experience it has been the exceptional graduate of the unusual private service who can match the good public ward service graduate in early clinical maturity, in habitual application of scientific knowledge, and in critique. Although not so sharply distinguishable in his forties as in his thirties (the able man, no matter where trained, inevitably passes any colleague who relaxes his effort), the ward-trained physician's familiarity with independent action under supervision, in addition to his technical skills, seems to have given him this initial lead and the habit of continued self-education.

The graduate of a pre-World War II senior residency has sometimes found himself prepared to undertake far more serious problems than his first private patients might have wished him to assume. Though lack of opportunity to take advantage of his training was perhaps briefly troublesome for the young physician's ego, few of his patients suffered purely by reason of his intensive hospital training for it often gave him experience for which physicians of previous generations had to wait many years in apprenticeships, and let him grow as fast as intellect and character permitted.

Read before the Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1953.

From the Department of Medicine and the Research and Educational Hospitals, University of Illinois College of Medicine, Cook County Hospital, and Chicago Memorial Hospital. Member, Advisory Committee on Internships to Council on Medical Education and Hospitals of the American Medical Association.

Many elements of the apprenticeship have survived in the public ward system in a broadened form consistent with the impact of microbiology, physics, chemistry, and psychodynamics on clinical practice. The medical student, released from the lecture room seat, became an apprentice of the intern at the bedside and in the clinical laboratory in his third and fourth years; the intern became the apprentice of the assistant resident. These younger residents, no longer bound to a single man in practice, served successively as apprentices of several men of diverse scientific and clinical skills.

The keynote in this type of residency was graded responsibility. At every level (medical student to senior resident), performance was under open appraisal. Those unfit by temperament or ability for further progression as a rule were as readily relieved of responsibility as those who were able were advanced. This has been often true for the attending staff. Hospitals devoted to teaching have effected ward staff changes with far fewer repercussions than are regularly occasioned when a physician's access to a private pavilion is limited or cut off. Ward beds may represent a physician's public service, his study, or his prestige. Private beds represent his livelihood. Independent private practice still fills the majority of private hospital beds in this country. It is, and must be, the core of our discussion. Most patients enter these beds because of the physician's individual standing in their eyes. The educational standing of his hospital is of lesser importance.

Every physician is in competition with at least some of his colleagues as well as others who profess, without formal medical training, to treat the ills of mankind. Often he is in competition with members of his own staff. Competition, in differing form, exists for privately or university-managed group practice. Most of the real and difficult educational problems that face private services stem from these facts. To meet them, factors determining local answers to these questions need evaluation. They vary for each medical center.

For the training of students and interns, the following questions might be asked: 1. What physician-patient and physician-physician relationships determine effectiveness when private patients are the teaching material? 2. Can the private services present a proper range and severity of illness? 3. Can the private service follow-up opportunities provide proper continuity of patient observation?

In training of residents, one might ask: 1. What physician-patient and physician-physician relationships affect the sharing and delegation of clinical responsibility for private patients? 2. How does teaching with private patients modify a physician's attitudes toward the incomplete nature of medical knowledge and the ritualistic aspects of medical practice? 3. In a teaching hospital with a large financial deficit, can the shift to private patients be done without the loss of educational standards? If not, what is the minimum proportion of public ward beds necessary? 4. If a private institution cannot afford this minimum, what determines success or failure of cooperative plans with tax-supported hospitals?

For all levels of teaching, one might ask: What factors have governed and what factors should govern the selection of attending staffs on private teaching services? What can be useful roles of trustees and of universities?

TEACHING OF CLINICAL CLERKS AND INTERNS ON PRIVATE SERVICES

The teaching hospital has been called the conscience of the medical profession, in providing a place in which questions must be asked, may be asked by anyone concerned with patient care, and must be answered if possible.[1] Such an atmosphere cannot but enhance standards of care for patients of any economic status, wealthy to indigent.[2] Let us, however, examine the patient's schedule for the first three hospital days on an average public ward. Day 1: (afternoon) admission history, physical examination done by intern and (evening) repeated, with routine laboratory work by fourth year clinical clerk. Day 2: (early morning) checked by resident and (midmorning) checked by attending physician on teaching rounds; (afternoon) two third year clerks arrive and fail to see the patient, who is undergoing roentgenographic studies. Day 3: (morning) third year clerks return to take a history and make a physical examination without looking at the chart; (afternoon) four to eight second year students elicit a halting history and laboriously stare at, feel, thump, and listen to designated body areas. A private patient will not submit to this type of schedule. The ward patient often does so through lack of an alternative.

Where the tact and humanity implicit in the golden rule obtains, the usual teaching exercises, such as bedside rounds, detailed case presentations, checking of physical findings, and amphitheater demonstrations, have been successfully carried out with private patients.[3] These courtesies are as follows: 1. Always ask both the patient's and the attending physician's permission. 2. Always tell the patient what to expect. 3. Never discuss details of diagnosis, therapy, or prognosis before the patient unless properly authorized. These rules are as applicable on a ward as on a private pavilion. Though the cost is irrelevant to teaching value at this level, there must be enough patients and with examples of pathological conditions corresponding to the serious pathological lesions the young physician will later encounter.

RANGE OF CLINICAL MATERIAL ON PRIVATE SERVICES

Though some physicians are destined to spend three-quarters of their lives treating patients with minor complaints, students, interns, and residents need as inpatients persons who are really ill. A backlog of hard-thinking experience acquired during youth with the seriously sick is invaluable to a career of sorting major from minor illnesses and to an appreciation of interactions of "organic" with "functional" factors. On some private services the range of disease compares with the best of teaching wards; on others it does not. The reasons for this are varied. A busy physician may find certain new patients hopelessly time-consuming for office schedules. A surgeon may find growth of practice coincident with increasing subspecialization. Each physician has an interest, both financial and human, in securing admission for his own patients. This can, but does not always, coincide with teaching interest. When interests regularly conflict, the private service encounters a problem in teaching material as serious as that of the university hospital that admits patients according to staff research interests. "Three-day work-ups" and "sales force check-ups" can ruin a private medical service for teaching as effectively as a predominance of rectal or industrial cases can ruin a general surgical service.

[3] Halsted, J. A.: The Role of the Nonteaching Hospital in Medical Education, New England J. Med. 243: 730-733 (Nov. 9) 1950.

Such patients have educational value only when (*a*) they are so selected that a high percentage reveal illness severe enough to warrant hospitalization and (*b*) the work-up of student and/or house officer is listened to and appraised and a plan of action and follow-up instituted before the patient's discharge. This has been successfully done on the residency level at the New England Medical Center's Pratt Diagnostic Hospital, Boston (Samuel Proger, M.D., chief),[4] and on the student level at Georgetown University Medical Center, Washington, D. C., (Harold Jeghers, M.D., chief of medicine).

Is the remedy to formulate hard and fast admission quotas for teaching needs and to put an experienced resident in charge of their day-to-day enforcement? From the resident's standpoint, the answer is no. True, the admitting resident on a public ward gets valuable training in rapid clinical judgment. Few sensible persons would want to screen admissions from a large practicing staff. The chances of remaining anyone's friend are small, no matter how astute or fair one may try to be. From the patient's standpoint, the answer is also no. His physician has screened him. From the senior administrator's standpoint, again the answer is no. He himself has no time to screen individual admissions. His usual lay admitting clerk scarcely can be expected to be sensitive to teaching values. This clerk can, however, record admission and discharge diagnoses for every patient and tabulate these, together with duration of stay, for every physician and every service. This shows which physicians carry the greatest daily responsibility for the spirit of the teaching hospital.

The first step in the remedy is regular publication of such a report to all involved in educational policy—to staff, administrators, and trustees. I have prepared representative tabulations for 1948 to 1951 for the department of medicine of the Presbyterian Hospital of Chicago. For such data, which are necessary for equable house staff assignments, it is unwise to rely on word of mouth reports from the house staff.

When an administrator finds difficulties in publication of the report, or the report is not read, this may reflect the wish of a significant part of the staff that education keep out of the way of existing practice. The admitting policy that cannot be subverted by persistent sabotage does not exist. When, per contra, publication is welcomed, the following questions come to open appraisal: What patients should not be assigned to the house staff or students? Should there be a "two-day limit" ward for emergencies, real or suspected? Should there be a unit for centralization of studies on long-term patients? Is an inpatient diagnostic unit needed? An inpatient diagnostic unit such as that at Columbia-Presbyterian Medical Center in New York (R. F. Loeb, M.D., physician-in-chief), can help to solve the teaching material problem mentioned above by segregating purely service work. Such a unit helps the physician who wants this work. It reduces the hospital's overhead on roentgenography and laboratory procedures. It can help the hospital's drive for funds, for it is not always the sickest patient who carries to the community the word that the hospital does a good job in service.

Highest standards of medical records and of personal performance of critical laboratory work can be successfully required of interns and students elsewhere in the hospital, where the records deal with real illness in contrast to the endless negative results and the complaint "we are being exploited as routine technicians" is validly eliminated. It should be noted in this connection that the recent report of the Advisory Committee on Internships [1] emphasizes these standards and recommends that personal performance of laboratory work be made mandatory during some phase of every approved internship.

Through study of such matters many hospitals have formulated workable admission policies aimed at needs of both education and practice. If they are wanted and backed by the staff and kept flexible and checked by the monthly admission data, chances of success are good with a minimum of cumbersome administrative rulings. Some hospitals enforce rigid regulation of a physician's admissions according to his role in the educational or research program. Applicable in university hospitals, such regulations are met less frequently in primarily service hospitals with teaching aspirations. If there is a keen general interest in teaching, it is feasible to assign house officers in terms of teaching performance, which includes a proper selection of patients for admission. This renders the hospital's competitive position for house staff less vulnerable to a staff minority.

The private services of the Barnes Hospital in St. Louis (Harry Alexander, M.D., chief) provide an example of policies regarding bed and house staff assignments in relation to teaching needs.[5] Policies regarding admission times for patients, etc., in relation to teaching needs are exemplified by the Emory University Hospital in Atlanta, Ga. (David James, M.D., chief of private medicine).

FOLLOW-UP OF PRIVATE PATIENTS

Without early establishment of habits of following the individual patient, the physician begins and may end by handling disease as a disembodied constellation of symptoms, signs, laboratory findings, and behavior characteristics artificially suspended in time by the accident of discontinuity in study.[6] Disease processes are not static, and the sequences need to be seen in embodied form.

On a private service great personal effort must supplement written schedules. The house officer must list patients on whom follow-up is wanted and arrange conferences flexibly enough to meet schedules of students and of the private physician.

The spontaneous development of staff groups interested in a certain type of disease can result in flourishing joint follow-up clinics. Patients are often under care of physicians in independent practice, as in the case of the work in psychosomatic disease at Michael Reese Hospital (Roy Grinker, M.D.), and the tumor clinic (representing surgery, medicine, pathology, and radiology) at Presbyterian Hospital (F. H. Straus, M.D.), Chicago. These clinics cannot be forced; spontaneity is their essence. Thus the emphasis of the psychiatric aspects of ordinary medical and surgical practice is impossible on private services where recent advances in psychodynamics are unfamiliar.

The private physician's share of effort is much more efficient if his office is in or near the hospital. If it is on the other side of the city, it is hard to persuade the busy patient to "drop over to the hospital next Tuesday so that Dr. X and Dr. Y who helped take care of you can join in observing progress."

This also goes for the busy private physician. When he has an office full of waiting patients some traffic-filled miles away, his daily answer to students and house staff can be, "Look, just do this, I've got to go." He goes, and they do as told. "Rounds and run" is as bad for the interchange of medical thought as "eat and run" for interchange at a dinner party. Thus offices close to the hospital can be as important to the community hospital with a good intern program as to the university center.

TEACHING ROUNDS AND CONFERENCES

The first American clinical professor of medicine described the function of teaching rounds for his hospital trustees in 1766 as follows:[7]

> There the clinical professor comes to the Aid of Speculation. . . . He meets his pupils at stated times in the Hospital . . . he asks all those Questions which lead to . . . knowledge of the Disease and Parts Affected, and if the Disease baffles the power of Art and the Patient falls a Sacrifice to it, he then brings his knowledge to the test, and fixes Honour or discredit on his Reputation by exposing all the morbid parts to view. . . .

The strong words of the Advisory Committee on Internships[1] add little beyond 20th century emphasis to Dr. Bond's thought.

Why do teaching rounds face special problems on private services? To be assured that all persons involved (student to resident) are working on the implications of every case takes time. The private physician already knows his patients to variable extents. Unless he also knows that properly stimulated students and the house staff will inevitably unearth some important fact about his patient he does not know or some pertinent literature he has not seen, he may regard the time of teaching rounds as wasted.

Then an occasional physician, skilled in running a large practice, finds himself ill at ease, even unable to talk, in guiding lively two-way communications between colleagues of grossly unequal experience. He feels as much out of place as many an inspiring teacher and researcher might feel in a busy private office.

Delegation of rounds is a valuable though partial solution. Despite the value for specialized (infectious disease, neoplastic) rounds, unless the private physician reserves some part of the bedside teaching for his own efforts, service *esprit de corps* suffers as badly as does his opportunity for continued self-education.

These precautions are a minimum: 1. Whatever the conclusions on teaching rounds, the program set up by the patient's own physician with the house staff must never be interfered with. 2. Questions of diagnosis or therapy must never be discussed within earshot of the patient or the patient's relatives. 3. Requests for a consultation with the physician in charge of rounds must in general be treated with great circumspection. When a physician says, "I'll take care of the patient; you do the teaching," he describes a workable division of labor only when there is real closeness between the two in technique and philosophy of medicine. Successful collaboration of full-time and practicing teachers was recently achieved on the private medical services at Johns Hopkins, Baltimore (Earle Moore, M.D., chief of private services).

Recently several private hospitals have sought as service chiefs men with records of good basic research and public ward teaching. Now granted no one is so effective in teaching bedside medicine as the laboratory-trained man who is equally at home with ears, eyes, hands, and deeper emotional sensibilities and who keeps the laboratory in proper perspective, yet the career full-time teacher has little experience with the complex system of loyalties, favors, and indebtedness that determines the daily events in a private hospital. His eagerness to benefit teaching can, in changing the old order of things, seem to his staff destructive. Accustomed to moving between investigative centers, he is not used to the need of a practicing physician for stability. In turn, many a practicing physician who wants a first-rank teaching program has not seen one in operation since he was a student and does not know the price in his time, tact, and thought. If there are difficulties, he is more likely to cooperate with a chief who at some period has had the same difficulties.

If many attending physicians, with or without cause to the outward eye, grow jealous of the men to whom teaching is delegated, teaching by two way communication dies. I have seen teaching die through jealousy toward no one more formidable than able residents. Revival through exercise of the authority of the dean or department head just does not happen. Thus I think the best leadership is achieved by a man who has spent a year or so in his own private practice or assisting an older man in practice before devoting full time to teaching.

Dr. Bond's rounds continued to the autopsy table when indicated. Today they would include many other laboratories. However, the critically important "death meeting" (where the sequence of each fatal case is discussed by all concerned) and the clinical-pathological conference may be impeded when a private physician feels the honest recognition of an error before his juniors may be used against him professionally. Though many staff members may be glad to "fix honor or discredit" on their reputations under proper auspices, pathologists and others with special knowledge have found it wise to be gentler with clinical colleagues than is customary in some of our famous ward amphitheaters and have done so without sacrifice of truth. In some places, however, the fear or undue professional discredit has been backed by an occasional concrete incident. The attitudes of teaching cannot be forced on a staff. A realistic appraisal of the hospital and community atmosphere becomes essential. Will time and medical statesmanship help? If not, efforts toward a first-class program may prove wasted.

[7] Bond, T.: The Utility of Clinical Lectures (1766), quoted in Flexner, A.: Medical Education in the United States and Canada, Bulletin 4, New York, The Carnegie Foundation for Advancement of Teaching, 1910, p. 4.

RESPONSIBILITY FOR PRIVATE PATIENTS ON ASSISTANT RESIDENCY LEVEL

In assistant residencies the young physician should begin to learn his more mature functions through supervised performance. These include explanations of therapy and prognosis, operative procedures, or special examinations and the giving of advice, encouragement, and when indicated, comfort, in addition to running the service smoothly. On a public ward service the role of assistant resident overlaps none other in these functions. House staff applicants often explain their preference for a public ward service by the phrase "greater chance for responsibility."

Thus a private service that hopes to attract applicants must provide some chance for action. If it does, I think a case can well be made for a private service's intrinsic superiority to a public ward at this stage of training. If not destructive in intensity, competitive practice can breed a matchless spirit of detailed attention to patients' needs. To be the junior teammate of a man versed in the humanities as well as skilled in the techniques of medicine can give lifelong illumination. When clinical responsibility is intelligently shared, the senior man wins a warm regard from his team that patients rarely fail to sense.

Unfortunately, some technically skilled physicians do not want a team; they want a retinue (patients rarely fail to sense this, either). These physicians do not want residents to order determinations of venous pressure, phenolsulfonephthalein tests, or other tests without specific authorization. To point out that on many private services responsibility is shared with benefits to the private physician, house officer, and patient is often useless. Some feel the patient's patronage depends on singlehanded direction of every detail; others have deeper private reasons. When a hospital's intern committee hears in the corridors, "We want fewer residents and more interns," chances for a good residency are slim.

Sometimes physicians will "delegate responsibility" if, and only if, the assistant resident has learned elaborate and rigid procedural patterns. Although a physician in a busy practice has often amassed considerable knowledge of techniques, when these become unchangeable then the service can only be said to "train" as animals are "trained." Its true educational function is valueless, save to those who have already learned the art of self-education.

Routines and rituals in medicine have a far deeper basis than utility as short cuts. The physician of today, with all the facilities of modern science at his disposal, is still like the temple physicians of the ancients in being asked to alter the course of many human maladies when he does not know how. Even psychoanalytic techniques, which have done so much to illuminate the role of symbolic ritual in human life, have themselves become so ritualized in certain circles that physicians endeavoring to apply scientific method in the further development have been excluded from psychoanalytic societies. Ritualistice aspects of care can be of value and are harmful today chiefly when dogged adherence blocks the adoption of more rational approach. On a private service there is opportunity to become aware of both the valuable and harmful sides of rigid procedures if the attending men have sufficient inward peace to be able to say "we don't know" with considerable frequency, to be able to discuss their own and alternative regimens without feeling their own functions as physicians are attacked. This inward security makes for a service discipline that, though apparently minimal in routines, is truly the most exacting of all. It is when they are headed by men of this type that I have seen private services clearly excel.

ADVANTAGES OF WARD BEDS FOR SENIOR RESIDENCY

The senior resident is ready to take charge of his own group of patients. In surgery this means operating, not only serving as first assistant. In other fields it means the responsibility for making major decisions and seeing that they get implemented.

For these, private patients pay their physicians. Here private beds cannot easily match the educational power of the well-run ward. Can a physician in practice delegate major clinical responsibility? Usually, no. Only under unusually favorable circumstances does the no become a weak yes. Most men who have themselves had the privileges of a real senior residency want them for their juniors and will work hard to set aside residency beds, though pressed in the early years of establishing practice.

Private patients who come to a hospital without a physician or are chosen by other criteria have sometimes been assigned to supervised senior residency care. Successful in some hospitals with senior residency tradition, this demands that the attending staff work as a team. The recent work of the Cornell University department of surgery (Frank Glenn, M.D., chief) is an important example at the New York Hospital. This service, despite difficulties, has had some success in senior residency training on private patients. The similarly organized program in medicine at Presbyterian Hospital, Chicago, that was previously reported [8] has had to be abandoned, in part through absence of staff support. The patient must always be told of the resident's role in the team. That the attending staff members feel free to do so is a good test of whether a hospital can be successful in giving a private patient senior residency care. Few indeed are the private services where the senior staff man feels he can step around the table to the first assistant position and permit the senior resident to perform the whole of a major operation. Almost no independently practicing surgeons feel free to do this. This is also true for private clinics operating wholly for profit. An intermediate policy obtains at one of the country's greatest private clinics, which, though dependent on patient fees, supports a large research and educational foundation. Here the staff tries to put its senior surgical fellows in charge during a part (not just the opening and closing) of every major procedure, in the hope that internal synthesis of the real but disjointed operative experience will lead to the same development of skill as the performance of whole operations. At the other limit stands a university-owned, nonprofit private hospital engaged in institutional practice, whose senior surgical resident functions as a full-fledged junior staff member.

[8] Cohn, E. J.: Research in the Medical Sciences, in Medicine Today: March of Medicine, 1946, New York Academy of Medicine, Lectures to the Laity, no. 11, New York, Columbia University Press, 1947.

Wherever heard, the query, "Is the hospital practicing in competition with us?" needs the further question, "How serious is this competition?"

When many of a staff have not had senior residency experience, they have trouble in making a senior residency more than an extension of the assistant residency. They feel the senior residency is superfluous. They point to many excellent men who never had one. Twenty years ago when the public ward system was most in use, the "pyramidal" residency progression provided few senior residencies in our teaching hospitals. Many who wanted them and were qualified never achieved these posts.

With the addition of private services, a great quantitative gain can come. In essence, we may thus multiply our senior residencies up to the real clinical resources of any given institution. It is vitally important that in so doing we do not go beyond these clinical resources.

The habit of self-education is not the property of any single training method. Yet refresher courses can never replace the habitual reading, observation, and self-scrutiny forced on the senior resident who takes major responsibility under the supervision of conscientious teachers. In the thousand years between Galen and the Renaissance, medicine made almost no advances. Techniques could be taught to apprentices with assurance that they would be as much a part of accepted practice in the physician's old age as in his youth. Today's rapid strides in basic sciences [8] make medicine's chances of becoming static again slight, but make the chances of failure to advance greater for the individual. Very few persons who have been senior residents fail to continue the habit of keeping up with advances in knowledge.

In view of these situations, some public ward beds are essential. How many? The ratio of 1 to 7 (public ward to private) is a useful approximation for hospitals with a total of 250 or more beds. The basis for this estimate has been published elsewhere.[9] This minimal figure highlights the situation in some private institutions whose senior residency programs are functioning inadequately from the educational standpoint and indicates that some traditionally great teaching hospitals could lower their presently larger ratios with consequent redistribution of funds toward other teaching and research needs without destruction of senior residency standards.

The fewer the ward beds, the more urgent is administrative and geographical centralization by major clinical departments under supervision of the heads of the departments or men chosen for ability in senior residency teaching. One of the problems of the private service house officer is that he may be responsible to a dozen attending men for 25 beds distributed through every floor and wing of the hospital. Centralization of ward beds gives a hospital a chance to study what centralization moves may prove timesaving teaching aids for the private services. Some men as they grow older and gain influence in a hospital manage to be relieved of much teaching work while keeping ward beds under personal jurisdiction. If a department's handful of ward beds is distributed between a half a dozen such jurisdictions, the chances of good senior residencies are slight. Independent action can be defeated by the necessity for multiple daily arrangements.

When, by reason of staff or finances, a private hospital cannot afford a minimal-sized ward service, affiliation with a publicly supported hospital can fill the lack. Some public and private institutions have been able to pool their characteristic resources in a successful cooperative program from the intern through the senior resident levels instead of having multiple programs inadequate in one or more features and in mutual competition. The history of educational affiliation between public and private institutions is characterized by wide variation in local practice and by many variations over the years. In some areas medical education has prospered by reason of stability of these relations; in others it has suffered as greatly for lack of them. It takes firsthand familiarity to grasp why these affiliations have proved so difficult some places but so fruitful when once established in others. This familiarity is needed to develop a workable plan free of obvious pitfalls for a given institution. Representative of some important new types of affiliation are the taking over of all operations of the municipal hospital in Nashville, Tenn., by Vanderbilt University (J. B. Youmans, M.D., dean) at a time when many Vanderbilt University Hospital beds have been converted to private use; the assignment of certain senior surgical fellows at the Cleveland Clinic (S. O. Hoerr, M.D., in charge of surgical education) to the Cleveland City Hospital for senior ward work (F. Simeone, M.D., chief of surgery). The Michigan plan of rural hospital and university hospital affiliation should also be considered.[10]

Often a city hospital staff will ask a private hospital seeking affiliation, "What can you offer us?" This has to be answered for success. Often with a little exploration, it can be. Research facilities are an example. When Francis Peabody [11] set up an investigative group under private auspices, with research laboratories and a small research ward in the midst of a great city hospital, he made a great contribution to the training of practicing physicians as well as of research men.

The aim is not to make a research laboratory of the hospital. To have a research program going side-by-side with patient care can breed an atmosphere of diligence and inquiry in clinical work that is hard to achieve in formal instruction. The critique (not the techniques) of investigation can be infectious and of lifelong value in practice. Given an institution-wide understanding that "applied research" is not always the most productive of truly valuable results, the presence of the urgency of disease close to the scientist's laboratory is a valuable prophylaxis against the artificial atmosphere of some isolated research institutes. Few city hospitals can provide such facilities with their own resources.

Thus the laboratories of the private hospital, often more extensive than those permitted by many municipal or county budgets, can truly implement the clinical care and basic medical facilities the latter provide. So also can its few ward beds, in giving special care when needed for special problems. Moreover, a private hospital, even in these tax-ridden days, has opportunities to seek financial support not always open to the municipal hospital directly and which are greatly strengthened by the latter's reservoir of clinical material. If, however, research is often used to enhance standing in competitive practice, resultant feeling may hurt the program. There may come a belief that the laboratory advantages of services staffed by a private teaching hospital will put other city hospital services in an unfavorable light or compete for staff with the research programs already set up within the city hospital. Any or all of these feelings, if sufficiently intense, can block fruitful collaboration. If the men on the affiliated services behave in a friendly and appreciative fashion and invite collaboration with other services when feasible, the adverse feelings we have described may dwindle to insignificance over a few years.

STAFFING THE PRIVATE TEACHING HOSPITAL

Given a city hospital affiliation for the senior residency, the core of a private hospital's teaching is still its own private services. A first-class service chief and house staff can maintain a high teaching standard on a public ward, even if some of the attending men give only minimum service required for patient care. For a private service, an enthusiastic chief and a keen house staff are not enough. Teaching enthusiasm and ability are needed in each private attending man.

When a service falls down in teaching performance, word goes from intern to prospective intern and from resident to prospect resident. With today's excess of house staff positions over candidates, a long time can be needed to reverse the trend of the service's drawing power. Though scarcely in a position to determine their curriculum, students and house staff are rarely deceived about the sincerity, interest, and intellectual integrity of their teachers.

So this question comes up: "Does a man uninterested in or incapable of teaching have a place on a private teaching service?" If staff selection is based on appraisal of long-term teaching promise in addition to usual bases of professional skill and loyalty, a hospital will face this question rarely.

Of great value in selection is a research program, backed by locally administered part-time fellowships. A private hospital with a clinical and scientific staff, chosen with consideration of cooperative work, has real investigative as well as educational value. Although few hospitals can afford research departments in all preclinical or clinical fields, many can afford one department with a creative scholar in charge, e. g., in pathology. The situation of the Presbyterian Hospital in Chicago is of interest (G. M. Hass, M.D., chief of pathology, D. A. MacFadyen, M.D., chief of biochemistry, and J. A. Campbell, M.D., chief of medicine). Having recently set up fundamental investigative laboratories on a scale rare among private hospitals with few public ward beds, it now faces the problem of comparable clinical facilities to give maximum use of its superb scientific plant in training practicing doctors and investigators. Though it is obvious that certain types of research are out of place at a private hospital, one of the greatest clinical investigators of our age, Sigmund Freud, worked almost exclusively with private patients. In investigative work, private hospitals face problems that a hospital with a public ward service under central direction does not. These arise from both the necessary admitting practices of the private hospital and from the occasional divergences in considerations of patient care from the standpoint of the private physician and scientific critique from the standpoint of the clinical investigator. With a staff united in purpose they can often be solved.

Local management of part-time fellowships permits local analysis of misuse that is not always possible with national full-time appointments. If a man expands his practice to the neglect of a paid part-time opportunity for teaching or research, this can be observed better with local administration than by a conference 5 to 10 years later to wrestle with the inadequate teaching function of his many beds. Most existing fellowships on a national or university level (such as the fellowships under the National Research Council, the U. S. Public Health Service, the Rockefeller Foundation, and the scholarships of the John and Mary Markle Foundation) are aimed at the development of the full-time teacher and investigator, not the teaching practitioner.

It is not easy to select men for teaching and research. One can be fooled by early adherence to the outward precepts of medical scholarship, which can cover a pervading paralysis of independent thought or action. On the other hand, when an able man (whose thirties are devoted to the demands of a young family and a confiscatory income tax rate) turns in his forties to the scholarly side of medicine, he often does more for teaching than the man whose encyclopedic knowledge has been acquired largely from books. The problem is finding this man in his burdened years—in differentiating him from the man whose practice, however large, is never quite large enough.

I have seen splendid teachers in 50-bed rural hospitals as well as in great medical centers. Nearly every man is a teacher of some effectiveness by the end of his house staff service. Then suppose he becomes an assistant in a very busy office and at the same time is given a dispensary morning assignment of students. He begins with enthusiasm. On busy days, he arrives at his private office late, sometimes without lunch, to find a full waiting room and his seniors or associate asking where he has been. Then he leaves this office late, misses dinner in handling the evening house calls, and comes home late to find his wife with the same question. Five years of this can put him in a bad teaching position unless his senior partners make certain that he has time to teach, read, and do some independent work. They are as responsible as he for his own development and for the teaching program of the hospital.

Whether through lack of time or of inclination, when the young man fails to study as he sees patients, he cannot keep up with advances in medicine; clinically immature students sometimes find themselves better prepared in the theory of medicine. It takes a lot of demonstrable practical sagacity to retain the respect of the students in this situation.

If several such young men become valuable private office assistants for capable senior teachers who try to secure permanent staff appointments for them, the finest of laboratories, full-time men, or research funds cannot offset the damage to the teaching program.

A lay board of managers or the administration of affiliated universities can help in setting standards, but within limitations. The lay board members of private hospitals are open to private persuasion by staff physicians who care for them and feel a serious conflict of loyalties in making decisions against the wishes of their own physicians. The occasional lay board member who makes an independent study of the processes of medical education can be of great service to a teaching program. This takes both devotion to duty and time, which is as valuable to business men as to physicians. Teaching is a collaborative job rarely fruitfully forced from the "outside," as by administration, and when it is forced, the relationship is unstable. Even when universities own hospitals, this is not always a sure safeguard against either exploitation or stagnation.

A private hospital should be prepared to provide beds for moderate-sized practices of some of an affiliated university's key investigative clinicians. (The hospital staff must insist on proper qualification for practice. More than one able scientist with a degree of doctor of medicine has been tempted to enter a clinical field without adequate training.) Because there exist rare instances of failure of function of whole clinical departments when one or two salaried staff members exploit practice privileges in competition with private physicians, to the neglect of teaching and research, it is essential to define borderlines between legitimate use and exploitation that will be valid locally.

Today many a full-time teacher in the old-fashioned sense is forced by family pressure to seek a source of additional income beyond his university salary. Salaries, particularly at the associate professor level, were barely adequate a decade ago and have not increased commensurately with taxes and inflation. The simplest administrative safeguard against exploitation of practice privileges is the setting of a maximum amount that a man can earn and the insistence on periodic reports. Any flagrant abuse is usually obvious.

Hospital staffs, which are self-perpetuating by promotion of faithful assistants, do not always welcome independent appointments by university authorities. If the staff depends on independent practice, behind such resentment is fear that a new man appointed for educational reasons (particularly if appointed at a top level) will use his teaching or research prominence to take over part of existing staff practices. It is important that full-time educators act in such a way as to make these fears groundless.

If a university depends completely on appointments of persons emerging from an entrenched clinical faculty (whether in private or institutional practice), the danger of self-perpetuation into mediocrity remains. The history of medical education is marked by many a battle between a university aiming at top educational standards and a staff aiming at preservation of seniority privileges. For every stalemate many superb collaborations have emerged. If a hospital staff is able to take the responsibility of examining its own appointments in the light of teaching and research, a university is wise to make clear its educational criteria, examine carefully and independently the men proposed, appoint those who fulfill them, and reject those who do not, with explicit statement of reasons, and go no further. Indeed, a few private hospitals with loose university affiliations have implemented this ideal by appointment of committees outside their own staff, including representatives of the basic sciences, to select key staff replacements. This is done at the Massachusetts General Hospital, Boston, Dean Clark, M.D., medical director.

When a university gives an initial three year appointment, it usually reviews the record before the end of that time. In many private hospitals the usual one year staff appointment given by the lay board is subject to renewal year after year without scheduled academic review. When private hospitals and universities affiliate, sometimes the university mistakenly takes the hospital's one year to mean a single year and therefore waives its own reviewing function. It is critically important for the private teaching hospital to inform every new man that initial staff appointments and academic rank are subject to joint review at stated periods and are mutually dependent.

If a university finds a hospital staff as a unit cannot meet its standards, often a very satisfactory distribution of good teaching services can be achieved by supporting individual services in several hospitals (good examples of this can be seen in certain private hospital services affiliated with Northwestern University in Chicago). Cumbersome as this arrangement may sound administratively, when the university influences only those services interested in its work and takes no part in the other services of a hospital, friction in hospital-university relations is often minimal. When a university takes over the function of supplying a house staff to approved services in several hospitals, it moves by hospital default into a central role in postgraduate medical education in addition to its traditional undergraduate role.

The final responsibility, however, for use of private beds in medical education belongs mainly to the private physicians. They become associated with teaching programs because of teaching interests and they seek to perpetuate their interest by staff recruitment. This is facilitated in communities where there are enough private beds; physicians without intense interest in teaching can voluntarily become associated with other hospitals without loss of efficiency in service to patients.

SUMMARY AND CONCLUSIONS

For teaching purposes it makes no difference whether the patients are in private rooms with baths or in 20 bed wards or whether their hospital charges and professional fees are paid by private insurance, the patients themselves, or public authorities if the following criteria are met:

1. The patients present the range of serious disease the young physician will meet later on. 2. The house staff and students can follow the course of the patients after discharge. 3. The staff members love to teach, realize that teaching takes valuable time and do not begrudge it, and cherish the continually broadening viewpoint arising from day after day exchange with younger colleagues. 4. The staff members are secure enough in relationships with patients to share responsibility with junior colleagues. 5. The staff members are sensitive to the difference between mere training and true education. Education presupposes training in the accepted concepts and procedures of the day and goes further in encouraging the student to explore and to face revisions with equanimity.

At the end of hospital training, when a real degree of skill and experience has been achieved, the senior resident is ready to take charge of his own group of patients in the teaching hospital. (In the surgical specialties this includes actual operating not merely serving as first assistant, and in the medical specialties the major diagnostic and therapeutic decisions.) For these functions, private patients pay their private physicians not hospital residents. Here private services cannot completely supplant the public wards.

A few private services over the country satisfy these criteria. Their teaching performance is attested by their popularity in attracting house staffs. Many do not. However good their educational programs look on paper, a few hours in the house staff dining room, a few days visiting the actual teaching exercises, and some hours on rounds with the attending staff disclose problems of patient population and in follow-up continuity, of attending staff selection and in provision of proper facilities for their practice and research to implement teaching, and of the necessity for a minimal ward service under central departmental control for senior residency training.

Most difficult of all are problems of physician-physician relationships. Their solution is critical to the success of the private service in the sharing and delegation of clinical responsibility essential for development of clinical maturity. The complexity of these difficulties leads me to feel that the success of the public ward system in teaching performance will not be matched by all private services in the near future.

Much of the working out of problems will depend on local conditions, such as whether the private hospital staff is open or closed, whether the supply of private beds meets demand, whether city hospitals welcome close teaching affiliations in a senior residency program, and whether private hospitals can give the city hospitals equal advantages in such an arrangement.

Success will depend on the persistence of those who believe in the role of private institutions in medical education. An old-fashioned public ward service can work well with a keenly interested chief and a handful of capable attending men as a faculty. Its capacity to give independent action to its house staff can offset many indifferent teachers. A private service can work well only if all persons involved understand the goal, want it, and will work for it.

1753 W. Congress St. (12).

FATAL STAPHYLOCOCCUS ENTERITIS FOLLOWING PENICILLIN AND STREPTOMYCIN THERAPY

Chester W. Fairlie, M.D.
and
Ralph E. Kendall, M.D., Hartford, Conn.

Fatal Staphylococcus enteritis following antibiotic therapy is now a familiar entity,[1] but its clinical picture and its exact relation to the several antibiotics remain to be clarified. Three cases of this entity were autopsied and are reported, with emphasis on the following aspects: 1. The clinical picture of this complication that can appear very soon after antibiotics are given and that may follow a fulminating course demands prompt therapeutic action. 2. All three of these patients received only penicillin and dihydrostreptomycin intramuscularly, in contrast to reports in the literature [1] in which aureomycin and oxytetracycline (Terramycin) administered orally have generally been the offending agents. 3. Some observations on pathogenesis are discussed.

Also described are two cured patients in whom the clinical picture was identical to that of the patients who died. Staphylococci were not cultured from the stools in these patients; but, in each case, throat and stool cultures showed abnormal flora. The concept that this complication arises from a suppression of the normal intestinal flora, which then permits the ever-present staphylococci to thrive to a pathogenic degree, seems oversimplified.

REPORT OF CASES

Case 1.—A 22-year-old white woman was hospitalized for exodontia and died six days later from fulminating enteritis. During the summer of 1952 this patient had been thoroughly studied because of a persistent mildly febrile illness, with no intestinal symptoms and with negative stool culture. The illness was considered probably to be rheumatic fever. The eventual autopsy did not yield any explanation of this illness.

The woman's dental condition was poor. After she seemed almost recovered from the mild febrile illness, she was admitted to the hospital for exodontia that was performed uneventfully on Nov. 28, 1952. Procaine penicillin G, 400,000 units, and dihydrostreptomycin, 1 gm., were given intramuscularly twice daily for five days, from Nov. 25 through

Nov. 29, 1952, as prophylaxis. On Nov. 30, the patient was discharged from the hospital feeling well. She was afebrile. On the day after discharge, nausea, occasional vomiting, malaise, periumbilical discomfort, and diarrhea, with two to three watery stools per day, developed. Three days after discharge, her temperature had risen to 104 F, and she was readmitted to the hospital. Her rectal temperature on admission was 106 F; pulse, 130 per minute; and blood pressure, 90/60 mm. Hg. The patient was lethargic, had constant liquid stools, and soon became semicomatose. The hematocrit was 44%, and the white blood cell count was 6,100 per cubic millimeter, with polymorphonuclears, 85%, lymphocytes, 9%, monocytes, 3%, and eosinophils, 3%. Urinalysis showed specific gravity, 1.020; albumin, 3 plus; no sugar; and coarsely granular casts, with a few red and white blood cells in the sediment. A blood culture was sterile. Nose and throat cultures on Dec. 3, 1952, yielded 4 plus growth of hemolytic Staphylococcus aureus.

The patient was given fluids intravenously, two intramuscular injections of procaine penicillin G, 400,000 units, and dihydrostreptomycin, 1 gm., and an intramuscular injection of cortisone. She rapidly grew worse. Six hours after admission, her blood pressure had dropped to 50/26 mm. Hg, and 12 hours after admission she died.

At autopsy, two and one-half hours after death, the gastrointestinal tract was contracted and devoid of normal content. The lumen of the upper small intestine, particularly, contained an elastic but friable semitranslucent mucoid material that formed a cast of the lumen and rugal folds. This material was present in the stomach, where it formed an incomplete cast. The colon was empty, and the mucous membrane was moist and hyperemic, but not ulcerated. The mucous membrane of the stomach, duodenum, and ileum was swollen and congested and showed small points of superficial erosion. Other body viscera showed congestion but no significant pathological changes.

Postmortem bacteriological study showed that the blood in the heart was sterile. The nasal sinuses contained proteus vulgaris and nonhemolytic streptococci. The small intestine yielded a pure culture of hemolytic Staph. aureus (coagulase positive), but no gram negative organisms were present. The colon yielded a pure culture of hemolytic Staph. aureus (coagulase positive). Microscopic examination of the stomach and small intestine, particularly, and, to a lesser degree, of the colon showed an intense congestion of the mucosa, with edema and inflammatory infiltration. The inflammatory reaction consisted of polymorphonuclear neutrophils, plasma cells, lymphocytes, and histiocytes. In some areas, these extended through the muscularis. In many places, there was superficial loss of surface epithelium. A marked proliferative mitotic activity of the glandular epithelium was present. The luminal cast was composed of interlacing, pink-staining strands and a finely granular ground substance that contained cellular debris and a moderate leukocytic infiltration throughout. Periodic acid and aniline water (Gram-Weigert) stains indicated that the cast was composed mainly of fibrin with a small amount of mucus enmeshed. The most striking feature was the presence of numerous colonies of staphylococci.

Case 2.—A 52-year-old white man had a subtotal gastrectomy on Jan. 15, 1953, because of a benign gastric ulcer. The patient was in good general health. His history, physical examination, and routine blood and urine studies indicated nothing abnormal. His blood pressure on admission was 140/94 mm. Hg. A gastric analysis showed 7 units of free acid before and 39 units after histamine was administered. Because of its high position on the lesser curvature, the ulcer was left in situ (after biopsies were reported benign), while two-thirds of the stomach was resected. The operation was uneventful; later autopsy confirmed the fact that no surgical complications had arisen.

On the first postoperative day, the patient received 400,000 units of procaine penicillin G and 1 gm. of dihydrostreptomycin intramuscularly at 8:00 a. m. and no other antibiotics on this day. When it was discovered that this man had a history of sensitivity to penicillin, this drug was not given again after the initial dose; thereafter, he received streptomycin alone. During the first postoperative day, his rectal temperature was between 100 and 101 F. His condition was satisfactory. On the second postoperative day at 8:00 a. m., the temperature was 101.4 F, and the pulse rate showed a sudden rise to 120 per minute; this was just 24 hours after the first injection of penicillin and dihydrostreptomycin. The second injection, of streptomycin alone, was not received until 1:00 p. m. on the second postoperative day. During this day, diarrhea began, with eight copious liquid stools in the 24 hour period. At 4:00 p. m., the rectal temperature was 103.4 F. The patient looked and acted well and stated that he felt fine. The lungs were clear to physical examination. On this day, the man received 1 gm. of streptomycin intramuscularly at 1:00 p. m. and at 9:00 p. m.

On the third postoperative day, the patient's temperature was between 105 and 105.8 F. In the morning, it was noted that he still did not appear very sick. The diarrhea continued with seven copious liquid stools. The chest was normal. The white blood cell count was 3,200 per cubic millimeter, with 89% polymorphonuclears. Blood culture made on this day was normal. Stool culture showed Esch. coli, nonhemolytic streptococci, but no enteric pathogens; it had been seeded on only the usual enteric medium, not including a blood agar plate. Streptomycin, 1 gm. intramuscularly, was given at 9:00 a. m. and 9:00 p. m. In the evening of the third postoperative day, the patient began to vomit, and it was evident that he was critically ill. On the assumption that he had sepsis of undetermined type, aureomycin was given intravenously. The patient received 5.5 gm. of aureomycin intravenously during the next 60 hours, with no evident change in his condition. On the next day, the temperature ranged to 103.6 F, and the diarrhea continued with six watery stools, a total volume of approximately 3,000 cc. The blood pressure fell as low as 60/40 mm. Hg during part of this day. The man received 1 gm. of streptomycin intramuscularly at 9:00 a. m., and intravenous administration of aureomycin was continued.

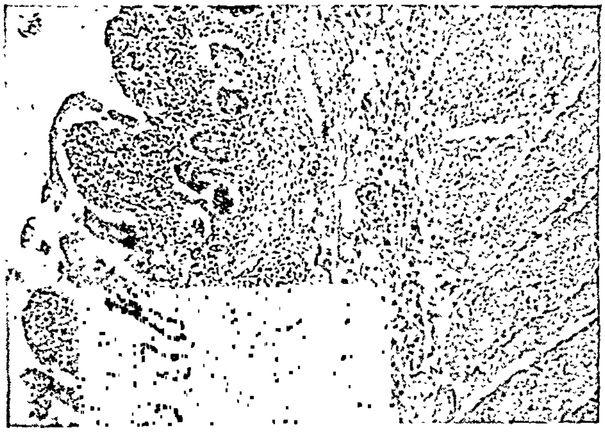

Fig. 1.—Photomicrograph showing infiltration and disruption of intestinal mucosa (case 2).

On the fifth postoperative day, the rectal temperature reached 103.6 F. The diarrhea ceased. The patient was critically ill, and his blood pressure remained at shock levels during most of this day. The white blood cell count was 13,000 per cubic millimeter, with 95% polymorphonuclears. Nonprotein nitrogen determination was 105 mg. per 100 cc. The patient's urinary output was 1,850 cc. on the first, probably normal (bathroom privileges) on the second, not known on the third, and reduced to 40 cc. and 75 cc., respectively, on the fourth and fifth postoperative days. This oliguria was presumably due, at least in part, to hypotension. A moderate deficit of sodium was evident, but deranged fluid and electrolyte balance did not seem severe enough to account for any important part of the patient's illness. On the fifth day after surgery, the patient received 1 gm. of streptomycin intramuscularly at 9:30 a. m., and intravenous administration of aureomycin was continued. The patient died at 4:00 a. m. on the sixth postoperative day.

At autopsy, two hours after death, the recent subtotal gastrectomy wounds were intact, without leakage, and with an adequate gastroenterostomy stoma. The peritoneal reaction was slight and consisted of delicate fibrinous adhesions without purulent exudate. There remained a 2 cm. indurated ulcer on the lesser curvature, 1 cm. from the cardia. The margins were sharp and not thickened. The duodenal limb and the entire small intestine were distended. The wall was thickened and edematous. The intestine contained light yellow, semifluid, mucoid material, and the mucous membranes were congested, edematous, and hemorrhagic. No blood was present in the intestinal lumen. The colon showed a similar, though less marked, reaction. No ulcerations or any formed fecal material were present. Other organs were moderately congested, but without other contributory pathological changes.

Postmortem bacteriological study showed that the blood in the heart was sterile. In the small intestine, hemolytic Staph. aureus (coagulase positive) was the predominating organism. Nonhemolytic Streptococcus was present, but there were no organisms of the colon group. Organisms in the colon were similar to those in the small intestine. On microscopic examination, the intestinal mucosa was congested, edematous, and diffusely infiltrated with plasma cells, lymphocytes, and a few polymorphonuclear cells in focal areas. The glandular epithelium was degenerated in isolated glands but, for the most part, showed proliferative mitotic activity. The histology of the small intestine is shown in figures 1 and 2. It was entirely similar in the other two autopsies. The stomach and colon showed similar though less intense changes. The other organs showed acute inflammatory bronchitis but no other significant abnormality.

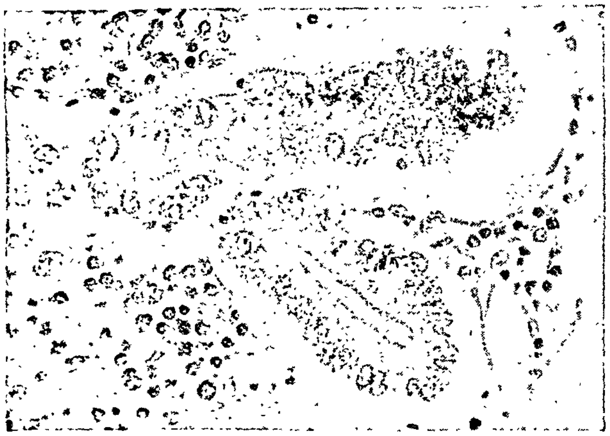

Fig. 2.—Photomicrograph showing proliferative activity of glandular epithelium (case 2).

Case 3.—A 61-year-old white man was admitted to the hospital on Jan. 23, 1953, for revision of an ileostomy. He had had chronic idiopathic ulcerative colitis of 18 months' known duration. Nine months before admission, an ileostomy was performed at another hospital because of profuse rectal bleeding. His general condition had improved greatly after this operation, with a weight increase from 110 to 138 lb. (49.9 to 62.6 kg.). The ileostomy had, however, been placed so near the iliac spine that no apparatus could be made to fit it. There was constant leakage and soiling, which was particularly bothersome at night. The patient had had a coronary occlusion two years before admission and anginal symptoms for five years. He was being maintained on digitalis, but there had been no frank episode of congestive failure. Although his cardiac condition clearly increased the risk of surgery, his situation had become intolerable to him, and revision of the ileostomy was considered necessary. Because of marked pathological changes in the colon, with pseudopolyposis, it was decided to perform a partial colectomy at the time of this operation. These procedures were carried out on Jan. 27, 1953.

On the day before operation, the patient received 400,000 units of procaine penicillin G and 1 gm. of dihydrostreptomycin intramuscularly in the morning and evening. On the day of operation, he received one such injection, and 1 gm. of streptomycin and 500,000 units of penicillin were placed in the peritoneal cavity. For the next eight days (through the eighth postoperative day), the man received two intramuscular injections daily of 400,000 units of procaine penicillin G and 1 gm. of dihydrostreptomycin. On the eighth, ninth, and tenth postoperative days (beginning after the onset of small bowel distention and ileostomy diarrhea), he received a total of 1.75 gm. of oxytetracycline orally. On the 11th and 12th days after surgery, he received no antibiotics. On the 13th postoperative day, he received one intramuscular injection of 300,000 units of procaine penicillin G.

The patient appeared to be doing well for three days after surgery. On the fourth postoperative day, he vomited several times, and there was moderate abdominal distention. During the next two days, symptoms and signs developed that were thought to be indicative of small bowel obstruction, with distended loops of small bowel visible roentgenologically. A Miller-Abbott tube was passed satisfactorily with free drainage, but it was noted that distended loops of small bowel were still present proximal to the tip of the tube, indicating paralytic ileus rather than mechanical obstruction. Copious green liquid drainage from the ileostomy was first noted on the seventh postoperative day. It continued copiously until death, or shortly before. Ileostomy drainage on the 11th postoperative day was 6,450 cc. On the 12th postoperative day, a physician recorded that there was "frank blood . . . and shaggy exudate" draining from the ileostomy. Fever was not present until the 12th postoperative day when the rectal temperature rose to 102.8 F and to 105 F the next day. Stool culture (from the ileostomy) on the 13th postoperative day showed 2 plus growth of hemolytic Staph. aureus (coagulase positive).

The patient's downward course was accompanied by progressive nitrogen retention and by moderate deficits in electrolyte concentrations. On the day before death, the blood nonprotein nitrogen was 68 mg. per 100 cc.; serum sodium, 126.5 mEq. per liter; serum potassium, 5.5 mEq. per liter; chloride, 83 mEq. per liter; serum albumin, 3.9 gm. per 100 cc.; and globulin, 3 gm. per 100 cc. On the 11th postoperative day, the blood pressure dropped to 80/70 mm. Hg. It was maintained at somewhat higher levels thereafter with the aid of vasopressor drugs; but for the last three days of illness, there was a state of semishock with marked oliguria. The patient died on the 14th postoperative day.

At autopsy, performed three hours after death, the operative wounds (revision of ileostomy and right hemicolectomy) were healing and without inflammatory reaction. The heart weighed 490 gm., and there was left ventricular hypertrophy. An old 7 cm. fibrous scar on the anterior aspect of the myocardium largely replaced the musculature. Posteriorly, a recent yellow-red infraction extending 3 cm. was seen. The left anterior descending coronary artery showed an old recanalized occlusion while the left circumflex artery, 3 cm. from the bifurcation, contained a recent thrombus. In the gastrointestinal tract, the esophagus and stomach were normal. The mucosa of the duodenum, jejunum, and ileum was edematous and congested. Petechial hemorrhages were present in the mucosa, diminishing in frequency in the lower intestine. The intestinal content was yellowish-brown and mucopurulent. In the portion of the colon and rectum remaining, the wall was thickened and the mucosa scarred, edematous, hemorrhagic, and covered with a mucoid material typical of chronic ulcerative colitis. Other body viscera were noncontributory. The kidneys weighed

300 gm. and had a smooth capsule and distinct corticomedullary markings.

Postmortem bacteriological study showed that the blood in the heart was sterile. In the ileum, hemolytic Staph. aureus (coagulase positive) was the predominating organism; there was a moderate growth of yeast cells and an occasional colony of Esch. coli. The colon yielded hemolytic streptococci (coagulase positive) but no gram negative organisms. Microscopic study of the ileum showed edema, congestion, and inflammatory infiltration with lymphocytes, plasma cells, and, in focal areas, polymorphonuclear cells. There was epithelial proliferation with mitotic activity. In the colon, fibrous mucosal and submucosal scarring was present together with moderate inflammatory reaction. The heart sections revealed acute and chronic myocardial damage. A peribronchial alveolar inflammatory infiltration was present.

Case 4.—Shortly after the patient in case 2 died, an identical condition developed in another patient, a 61-year-old man who also had just had a subtotal gastrectomy. The operation had been uneventful. Beginning on the day of operation, the patient received 400,000 units of procaine penicillin G and 1 gm. of dihydrostreptomycin intramuscularly twice daily. On the next day, the patient had a rectal temperature of 102 F, which rose to 103.8 F on the second and third postoperative days. On the third postoperative day, diarrhea commenced with six to eight liquid stools per day for the next three days. Meanwhile, the patient looked and felt surprisingly well, as had been true also of the patient in case 2. With fever of 103.8 F in a postoperative patient, one is ordinarily inclined to begin, or to increase, antibiotic therapy. In view of recent experience, however, all antibiotics were discontinued early in the fourth postoperative day. The striking cessation of fever and diarrhea that followed is shown in figure 3. The patient thereafter recovered uneventfully.

Stool cultures (including blood agar plates in each instance) were performed from the second through the seventh and on the tenth day after the beginning of diarrhea. At no time did they show staphylococci. Esch. coli was present in all specimens. There was an abnormally abundant growth of enterococci beginning on the fifth day, and this was still present on the tenth day after the beginning of diarrhea (the latter culture was grown nine days after antibiotics were discontinued and six days after diarrhea had ceased). Cultures from the throat and sputum on the fifth postoperative day showed 2+ and 4+ growths of Staph. aureus, respectively.

Case 5.—A 61-year-old white man had an uneventful herniorrhaphy on March 31, 1953. Subsequently, a barium enema was performed because of a history of lower abdominal symptoms. The enema led to the discovery of what proved to be a subacute appendiceal abscess. On operation on April 10, 1953, it was necessary to do a partial colectomy to remove the inflammatory mass. In the 24 hours following this operation, the patient received two intravenous injections of 0.5 gm. of oxytetracycline. He received no other antibiotics at any time. None were given at the time of the previous herniorrhaphy.

On the second postoperative day (24 to 36 hours after the beginning of administration of oxytetracycline), the patient's temperature rose to 104.6 F rectally, and watery diarrhea, 11 stools with a total volume of approximately 3,000 cc., began. Peristalsis was hypoactive, and there was moderate abdominal distention despite the fact that a Miller-Abbott tube had been inserted immediately after operation. The white blood cell count on the first postoperative day was 14,200 per cubic millimeter, with 84% polymorphonuclears. Blood culture taken at the peak of fever was normal.

Treatment consisted of discontinuing the antibiotic and of close attention to maintenance of fluid and electrolyte balance. Eight hours later, the man's temperature had dropped to normal, and it remained so. Diarrhea lessened on the third postoperative day, although it did not cease until the sixth postoperative day. The stool volumes on the third, fourth, and fifth postoperative days were 1,700, 805, and 935 cc., respectively. During these days, the patient made steady improvement but was still fairly sick as indicated by weakness, nausea, hypoperistalsis, and mild abdominal distention despite the Miller-Abbott tube. Thereafter, recovery was uneventful.

The patient's blood pressure was well maintained throughout. There was no azotemia; the serum nonprotein nitrogen was 40 mg. per 100 cc. on the third and 26 mg. per 100 cc. on the seventh postoperative day. Urinalyses, however, on the third and fourth postoperative days showed 4 plus albuminuria, with occasional white and red blood cells in the sediment but no casts. Urinalyses before operation and on the sixth and seventh postoperative days were entirely normal. Cultures of the pharynx and the stools (including blood agar plates) were taken on the evening of the second postoperative day (48 hours after the first of the two doses of oxytetracycline). The pharynx at this time showed a pure growth of Proteus vulgaris; the stool showed almost pure growth of the same organism, with no Esch. coli present. Proteus vulgaris from the pharynx was sensitive to chloramphenicol (Chloromycetin) and slightly so to dihydrostreptomycin. It was not sensitive to oxytetracycline or aureomycin. Pharyngeal cultures on the fourth and seventh postoperative days still showed pure growth of Proteus vulgaris. Stool cultures showed pure growths of Proteus vulgaris on the second, third, and fourth postoperative days with some Esch. coli present for the first time on the sixth postoperative day. Stool cultures on the 11th postoperative day still showed abundant Proteus vulgaris together with Esch. coli. No staphylococci were found at any time.

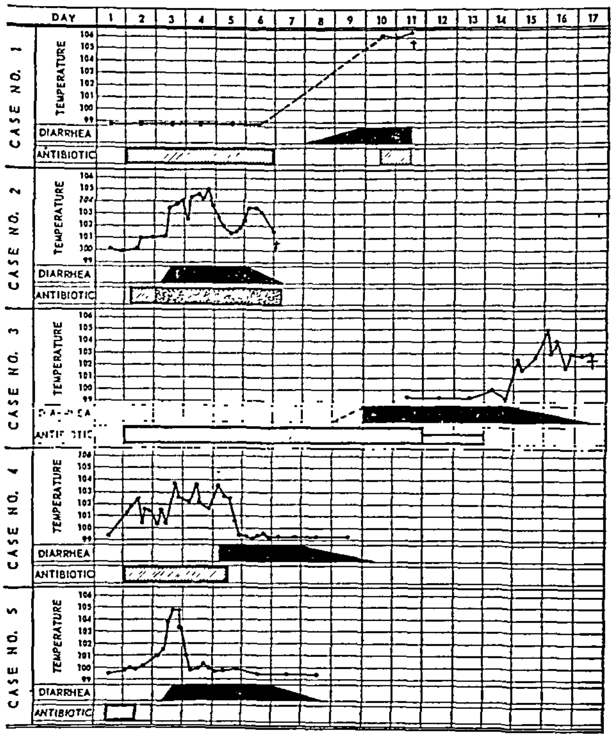

Fig. 3.—Postoperative courses of patients in case reports: cross-hatched rectangles indicate duration of therapy with penicillin and dihydrostreptomycin; stippled rectangles, dihydrostreptomycin only; and white rectangles, oxytetracycline (Terramycin) only. Solid areas indicate presence of diarrhea.

The illness of these two patients (in cases 4 and 5) appeared to be clinically identical with that seen in those that at autopsy were found to have Staphylococcus enteritis. In both instances, throat and stool cultures showed an abnormal flora, although staphylococci were found only in the throat cultures in case 4 and not at all in case 5. Hence it is considered that the illness of these two patients was due to toxins produced by intestinal bacteria under the influence of antibiotics.

COMMENT

Autopsy in each of the patients who died showed severe enteritis as the cause of death, with abundant and pure growth of hemolytic Staph. aureus in postmortem cultures from the bowel. All patients except one received combined procaine penicillin G and dihydrostreptomycin intramuscularly.

Fever and diarrhea were the cardinal clinical features at the onset of this condition. Two patients appeared strikingly well, clinically, during the first few days of this fatal complication, even though there was fever of 102 to 104 F and death was to ensue in four days. Shock, oliguria, and azotemia were prominent features in the later course in those patients who died. Diarrhea or fever began in these five cases on the second, third, seventh, and ninth days, respectively, after the beginning of administration of the antibiotic (fig. 3), and death occurred on the fourth, fifth, and eighth days after the onset of fever or diarrhea. Death appears to have been due to toxemia, not septicemia, since blood cultures during life and at post mortem were normal and since there was no evidence of pyemia.

The treatment of this condition includes the recognition of the complication as a possibility when unexplained fever or diarrhea develops in any patient receiving antibiotics. Recognition should be followed by prompt withdrawal of the antibiotics and, perhaps, by the use of an antibiotic to which most staphylococci in the patient's geographical area are known to be sensitive; for example, the use of erythromycin has recently been reported.[1b] In two of the present three cases, the Staphylococcus grown post mortem was not sensitive to penicillin, streptomycin, aureomycin, or oxytetracycline but was sensitive to chloramphenicol and magnamycin. The third organism was not tested. Because of the fulminating character of the illness, therapy should not be deferred until the results of cultures or sensitivity tests are known. Clinical recognition may be delayed by the fact that stool cultures during the first days of diarrhea may show normal flora and no staphylococci. This fact is supported by a sixth patient, seen more recently, in whom stool culture on the second day of diarrhea showed normal flora and no staphylococci. Twenty-four hours later, a stool culture showed pure growth of hemolytic Staph. aureus, with no Esch. coli present. The patient recovered. The dramatic termination of fever in cases 4 and 5 on discontinuance of the antibiotics suggests the advisability of a brief trial of this measure alone, if the patient is not in critical condition. The associated disturbance in fluid and electrolyte balance demands prompt and careful attention.

Simple suppression of intestinal flora permitting overgrowth of the Staphylococcus or possibly of other organisms does not seem sufficient explanation of this complication. Other factors might include the introduction of a particular strain of staphylococci or a direct stimulation of toxin production by staphylococci under the influence of antibiotics. The onset of fever and diarrhea as early as 24 hours after antibiotics were first given strongly suggests a stimulating action by these drugs rather than an effect secondary to suppression of the normal intestinal flora. This view is strengthened by the fact that in all cases the drugs were given parenterally only and by the fact that early cultures failed to show staphylococci. That antibiotics can stimulate growth of bacteria in vitro has been demonstrated.[2] Chronic upper respiratory infection, achlorhydria, and cessation of food intake are other factors that might influence changes in intestinal flora. Their role in these cannot be determined.

This condition should be considered not as Staphylococcus enteritis, but as toxicity from disturbed intestinal ecology. It should be emphasized that its manifestations include not only enteritis but systemic toxic effects such as hypotension and azotemia and also that the exact role of the Staphylococcus in this disturbance is not yet clear.

SUMMARY AND CONCLUSIONS

Three autopsied cases of fatal Staphylococcus enteritis occurring after prophylactic use of penicillin and dihydrostreptomycin are presented, together with two cases in which prompt discontinuance of antibiotics was followed by recovery from what appeared to be an identical condition.

The concept that this complication is due to suppression of normal intestinal flora permitting pathogenic overgrowth of intestinal staphylococci appears to be oversimplified. A direct stimulation of the Staphylococcus by antibiotics must be considered. Fever or diarrhea appearing in a patient receiving antibiotics should immediately suggest this complication. Prompt discontinuance of antibiotics and attention to fluid and electrolyte balance are the primary therapeutic measures.

Penicillin.—In the early days of penicillin the manufactured product was very impure and sometimes gave considerable pain on injection. To counteract this, procaine was often mixed with the penicillin solution in the syringes. Sometimes, it was noticed that a precipitate formed, but this did not affect the potency of the penicillin.

Later it was found that procaine formed with penicillin a salt that was only slightly soluble in water and, when introduced into the body as a suspension, was slowly dissociated. As with the oil-wax mixture, a dose of 300,000 units persisted in the blood for 24 hours. It was found also that if aluminum monostearate were added to the oily suspension of procaine penicillin the dissociation was further delayed so that a single dose would last for three days. Procaine penicillin made the treatment much easier for both doctor and patient, but the slow absorption meant that there was never a high concentration in the blood. To overcome this drawback, soluble sodium penicillin was often given in combination with the relatively insoluble procaine salt. This ensured a high initial concentration in the body, together with a long-continued action. More recently other salts of penicillin have appeared.

Diethylaminoethyl-ester hydroiodide of benzyl penicillin is a sparingly soluble salt that forms a depot like the procaine salt. Its peculiarity is that it appears to have an affinity for the inflamed lung and appears in much higher concentration in the sputum. This should be of advantage in the treatment of lung conditions.—Sir Alexander Fleming, The Shattuck Lecture: Twentieth-Century Changes in the Treatment of Septic Infections, *The New England Journal of Medicine,* June 18, 1953.

TREATMENT OF ACTINOMYCOSIS WITH ISONIAZID

Leon V. McVay Jr., M.D.
and
Douglas H. Sprunt, M.D., Memphis, Tenn.

The remarkable development of antibiotics and chemotherapeutic agents in recent years has resulted in improved methods of treatment in many infectious diseases; however, despite exhaustive clinical and laboratory investigations, many fungous infections continue to be generally fatal.[1] The commonest of these diseases is actinomycosis.[2] Although radiation therapy and surgery [3] are of value in localized actinomycotic infections, the sulfonamides and penicillin provided the greatest improvement in the prognosis of this mycotic disease.[4] Nonetheless, even with these agents the morbidity and mortality remained significant.[5] Recently aureomycin was demonstrated to be effective in the treatment of this condition.[6]

While searching for an inexpensive, effective, and nontoxic therapeutic agent for use in actinomycosis, isoniazid (Nydrazid) was considered. Isoniazid was recently demonstrated to be of value in tuberculosis.[7] Inasmuch as it has long been recognized that the tissue reaction and clinical picture in tuberculosis and actinomycosis are very similar,[8] it was decided to investigate the action of this agent in actinomycotic infections. The present paper constitutes a report of isoniazid therapy in three cases of localized actinomycosis.[9]

REPORT OF CASES

CASE 1.—A 9-year-old Negro girl was observed in the Antibiotic Clinic of the John Gaston Hospital and the University of Tennessee College of Medicine on June 2, 1952. This patient was referred by the Pediatric Clinic because of a persistent cutaneous lesion overlying the right mandible, of about three years' duration. In April, 1949, this patient had a severe toothache in the right lower jaw. All discomfort disappeared without dental treatment in three days; however, within a week an area of painless and nontender induration developed over the right lower jaw and persisted unchanged until May 14, 1952. Thereafter, progressive swelling was observed associated with moderate tenderness and trismus. On May 17, 1952, the lesion drained spontaneously, and the child was brought to the Pediatric Clinic of the John Gaston Hospital. No clinical improvement followed the administration of 2 gm. of sulfadiazine daily for a week. Therefore, the patient was referred to the Antibiotic Clinic for fungal studies.

Examination on June 2, 1952, revealed a chronic granulomatous lesion of woody consistency overlying the right mandible (fig. 1*A*). The area of involvement measured 2.6 by 2 cm. in diameter. A small amount of thin, yellowish material was draining from the orifice of a sinus located toward the periphery of the lesion. It was possible to pass a small probe along this sinus tract for a distance of 1.4 cm. There was no extension of the process into the oral cavity. A moderate degree of trismus restricted the separation of the anterior teeth to 2.9 cm. Dental consultation and roentgenologic studies revealed a periapical abscess about the roots of the right first molar tooth. No other abnormality was noted. Examination of the seropurulent material draining from the sinus disclosed the characteristic sulfur-like granules of Actinomyces bovis. The diagnosis of actinomycosis was subsequently confirmed by microscopic and cultural methods.

Isoniazid therapy was begun on June 12, 1952, in a dose of 300 mg. per day; 100 mg. was administered every eight hours. Inasmuch as the child weighed 73 lb. (33.2 kg.), this was approximately 9 mg. per kilogram of body weight per day. Because of the possibility of toxic effects resulting from dosage of this magnitude in such a young person, the patient was carefully examined each week in the Antibiotic Clinic, with especial attention being focused on the nervous system. In addition, comprehensive hematological, hepatic, and renal studies were made at weekly intervals. Slow but progressive improvement was noted. By July 16 (after five weeks of treatment), the area of involvement was sharply circumscribed and measured only 0.5 by 0.4 cm., the anterior teeth could be separated 3.6 cm., and the only complaint was intermittent mild pruritus about the lesion. Nevertheless, a small amount of thin purulent material continued to exude from the sinus orifice, and a culture obtained on July 3 yielded A. bovis; however, no sulfur granules could be detected. Since no toxic effects had been noted, it was decided to double the amount of medicament and to observe the child every other day. Rapid improvement ensued. By Aug. 19 it was possible to discontinue medication, inasmuch as the lesion had entirely epithelized, and the patient was completely asymptomatic. Only a small area of induration marked the location of the previous lesion (fig. 1*B*). On Sept. 28, the first right molar tooth was extracted without difficulty and with no sequelae. This patient has now been observed for six months and shows no evidence of recurrence of infection. In vitro sensitivity studies made with the organism isolated from this patient demonstrated a definite inhibitory effect by isoniazed on this strain of A. bovis (see table).

Sensitivity of Actinomyces Bovis to Isoniazid

— denotes inhibition.
+ denotes lack of inhibition.

The white blood cell count ranged from 12,000 to 7,400 per cubic millimeter, and the hematocrit from 35.5 to 40%. Urinalyses were persistently within normal limits. The sedimentation rate (Wintrobe, corrected) varied from 0.9 to 0.4 mm. maximal fall per minute (Rourke-Ernstene technique), the blood nonprotein nitrogen from 25 to 31 mg. per 100 cc., and the total protein from 6.6 to 7.9 gm. per 100 cc. with albumin from 4.2 to 5.2 gm. per 100 cc. and globulin from 2.4 to 2.8 gm. per 100 cc. Total serum bilirubin ranged from from 0.2 to 0.28 mg. per 100 cc.; sulfobromophthalein (Bromsulphalein) retention (after 45 minutes and with 5 mg. per kilogram of body weight intravenously) was 0 to less than 5%; cephalin-cholesterol flocculation tests were persistently 0 at 24 hours; and total plasma cholesterol from 122 to 172 mg. per 100 cc. with the cholesterol esters from 48 to 82%. Three cultures were negative for tubercle bacilli; the intradermal tuberculin test (purified protein derivative—first strength) was negative at 48 hours, but the second strength

---

E. R. Squibb & Sons, New York, supplied the isoniazid (Nydrazid) used in this study.

Because of lack of space, the bibliographic references have been omitted from THE JOURNAL and will appear in the authors' reprints.

From the divisions of medicine, pathology, and bacteriology of the University of Tennessee College of Medicine and the John Gaston Hospital.

purified protein derivative tuberculin test resulted in 1+ at 48 hours. A chest roentgenogram was interpreted as being within normal limits.

The clinical response and the in vitro sensitivity studies in this case indicate that isoniazid is effective in localized actinomycosis. It would appear that larger amounts of medicament are required in actinomycosis than in tuberculosis. Had 600 mg. (18 mg. per kilogram) been administered from the beginning of treatment, a more rapid clinical response probably would have occurred. Although this 9-year-old child received 30 gm. of isoniazid over a period of 67 days, no toxic effects were observed.

Case 2.—A 69-year-old Negro woman was referred from the General Medicine Clinic to the Antibiotic Clinic of the John Gaston Hospital on June 10, 1952, with the complaint of a mass in the neck. Approximately four weeks previously the patient noted a slight swelling in the left supraclavicular space. During the ensuing week, there was a marked increase in the size of the lesion and the area became moderately tender and warm to the touch. Very little change was noted in the following three weeks. There were no chills, no weight loss, no weakness, and no anorexia. No history could be elicited of trauma, syphilis, upper respiratory infections, or contact with tuberculosis. Examination revealed a mass in the left supraclavicular space extending upward over the lateral aspect of the base of the neck. This lesion measured 2.2 by 3 cm. in its greatest diameter and was moderately tender and warm on palpation. A small fluctuant area was present along the medial border of the mass. No other significant findings were observed.

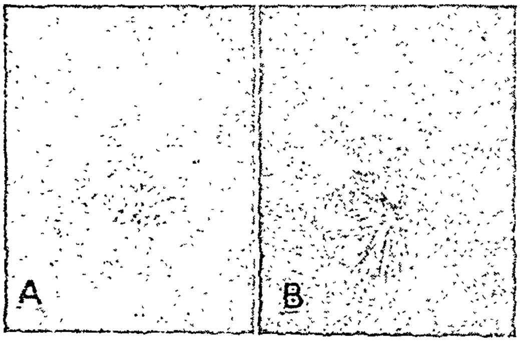

Fig. 1.—Chronic granulomatous lesion overlying the right mandible in case 1, before (*A*) and after (*B*) isoniazid therapy.

The fluctuant area was aspirated by aseptic technique, and about 2 cc. of rather thin, brownish-yellow material was obtained. Sulfur-like granules were readily demonstrated. Subsequently bacteriological studies yielded Mycobacterium tuberculosis and A. bovis. After aspiration chronic drainage developed.

Isoniazid therapy was begun on Aug. 7, 1952. This patient was treated entirely on an ambulatory basis, since hospitalization was refused. It was decided to administer 800 mg. of isoniazid daily—200 mg. four times a day. Inasmuch as the patient weighed 125 lb. (56.8 kg.), this was 14.1 mg. per kilogram of body weight per day. Because of the amount of medicament employed, the patient was observed every third day and comprehensive laboratory examinations were obtained to detect any evidence of toxicity. There was rapid clinical improvement. By Aug. 21 (two weeks after the institution of treatment), all drainage had ceased and there had been a marked reduction in the size of the lesion. Neither heat nor tenderness could be detected on physical examination of the lesion. Inasmuch as the patient's only complaint was moderate dizziness, treatment was continued. Two weeks later (Sept. 4), epithelization was complete. In addition to the dizziness, which had remained unchanged, the patient now complained of a slight tingling sensation in the fingers and toes; all reflexes were normal, and no neurological abnormality could be detected. Medication was discontinued on Sept. 16. On that date only a small area of induration was present. The patient was entirely asymptomatic and had gained 2 lb. (0.9 kg.) while under treatment. In vitro sensitivity studies using the strain of A. bovis isolated from this patient demonstrated a definite antagonistic action by isoniazid (see table).

The white blood cell count ranged from 10,200 to 8,400 per cubic millimeter with persistently normal differential determinations, the red blood cell count from 4,180,000 to 4,420,000 per cubic millimeter, and the hematocrit from 37 to 40%. All urinalyses were within normal limits. The sedimentation rate (Wintrobe, corrected) ranged from 1.4 to 0.9 mm. maximal fall per minute (Rourke-Ernstene technique); the blood nonprotein nitrogen from 29 to 25 mg. 100 cc.; total protein from 6.8 to 7.2 gm. per 100 cc. with albumin from 4.1 to 3.7 gm. per 100 cc. and globulin from 2.7 to 3.5 gm. per 100 cc.; cephalin-cholesterol flocculation from 0 to 2+ at 24 hours; and total plasma cholesterol from 156 to 119 mg. per 100 cc. with cholesterol esters from 68 to 75%. The Kahn blood test was negative. The intradermal tuberculin test (purified protein derivative—first strength) was 2+ at 48 hours. Two chest roentgenograms were interpreted as being within normal limits.

Isoniazid was apparently the drug of choice for the treatment in this case, inasmuch as it was effective against both the tubercle bacillus and A. bovis. Although this patient received 14.1 mg. per kilogram per day of isoniazid for 42 days (a total of 33.6 gm.), no significant toxic effects were noted. Mild dizziness was experienced on the sixth day of treatment and persisted unchanged; mild tingling in the extremities developed during the third week of therapy. Both of these side-effects disappeared within two weeks after medication was discontinued. There has been no evidence of recurrence of infection in the five months since the completion of therapy.

Case 3.—A 29-year-old Negro man was referred from the Orthopedic Clinic to the Antibiotic Clinic of the John Gaston Hospital and the University of Tennessee College of Medicine on June 25, 1952, because of a chronic lesion involving the right zygomatic area of the face. This patient had been hospitalized in the Orthopedic Service from Feb. 11 to March 1, 1952, after an automobile accident in which he sustained a comminuted fracture of the upper one-third of the shaft of the right tibia, a simple fracture of the right fibula, a fracture of the transverse process of the fourth lumbar vertebra, brain concussion, and multiple lacerations of the face and lip. While in the hospital he received 300,000 units of penicillin intramuscularly each day. Shortly after being discharged in March, the patient noted an area of nonpainful and nontender swelling, which involved the right superior portion of the face. During the latter part of May facial tenderness developed, and he was referred to the General Surgery Clinic, where the clinical impression was cellulitis of the face. This resulted in his admission to the Surgical Service of the John Gaston Hospital on June 3, 1952. Incision and drainage were performed on June 5. This procedure was reported to reveal a deep lying abscess over the right zygomatic process, which contained approximately 10 cc. of purulent necrotic material. From June 3 to June 5, the patient received 300,000 units of penicillin intramuscularly every 3 hours and 0.5 gm. of streptomycin every 12 hours; from June 6 until he was discharged (June 11), medication consisted of 100,000 units of penicillin every 3 hours and 0.5 gm. of streptomycin every 6 hours; thereafter, until the patient was seen in the Antibiotic Clinic, he was given 4 gm. of sulfadiazine daily (total of 60 gm. orally). Inasmuch as tenderness and swelling persisted, the patient was referred to the Antibiotic Clinic for further studies.

Examination on June 25 revealed an indurated area of woody consistency that measured 6.5 by 5 cm. overlying the right zygomatic area and extending superiorly almost to the lower eyelid. Minimal trismus was present. A moderate amount of seropurulent material was draining from a sinus tract located in the line of the previous incision and drainage. Gross and microscopic examination of this exudate revealed numerous sulfur-like granules. A culture of this material yielded A. bovis.

The patient was immediately given isoniazid, 700 mg. per day. Since the weight was 165 lb. (75 kg.), this constituted 9.3 mg. per kilogram of body weight per day. Gradual but definite improvement was observed and by July 17 (22 days after the institution of therapy) all drainage had ceased. No tenderness was present, and the anterior teeth could be separated 5.2 cm.; however, the patient complained of severe nausea associated with the ingestion of the medicament. Nausea was said to occur regularly about 5 minutes after medication and to persist for 10 to 15 minutes. The presence of food in the stomach markedly reduced the nausea. Vomiting did not occur. Isoniazid therapy was discontinued on July 24 after 28 days of treatment, inasmuch as the lesion had apparently epithelized and the supply of medicament was temporarily exhausted. Nine days later (Aug. 2) a painless, slightly tender area was observed approximately 0.5 cm. below the right eye. Needle aspiration of this area was carried out with aseptic technique, revealing a minute amount of yellowish material. Immediate gross and microscopic examinations revealed atypical granules. The filaments comprising these sulfur-like granules were quite loosely arranged, suggesting some degenerative action (fig. 2). No growth occurred in culture. Since the patient was quite depressed and no isoniazid was immediately available, he was given aureomycin, 3 gm. daily for 10 days and then 2 gm. for 18 days. By Nov. 10, 1952, epithelization was complete and no swelling or tenderness was present. In vitro sensitivity studies using the organism obtained from this patient again revealed a definite inhibitory action by isoniazid against A. bovis (see table).

The white blood cell count ranged from 10,200 to 6,000 per cubic millimeter, and the hematocrit from 41 to 45%. Repeated urinalyses were within normal limits. The sedimentation rate (Wintrobe, corrected) ranged from 1.4 to 0.6 mm. maximal fall in 1 minute (Rourke-Ernstene technique); the blood nonprotein nitrogen from 29 to 33 mg. per 100 cc.; total serum bilirubin from 0.28 to 0.84 mg. per 100 cc.; and total protein from 7.3 to 7.6 gm. per 100 cc. with albumin from 4.2 to 4.6 gm. per 100 cc. and globulin from 2.7 to 3.2 gm. per 100 cc. The cephalin-cholesterol flocculation test was persistently 0 at 24 hours, and total plasma cholesterol varied from 162 to 198 mg. per 100 cc. with cholesterol esters from 50 to 71%. The Kahn blood test was negative, as was the intradermal tuberculin test (purified protein derivative—first and second strengths). Comprehensive roentgenologic examinations were nonrevealing.

This patient received much less isoniazid than did the other two patients, only 19.6 gm. as compared with 30 gm. and 33.6 gm., respectively. Nevertheless, gradual but definite evidence of improvement was observed. The morphological alteration of the sulfur-like granules demonstrated after the administration of isoniazid and the fact that A. bovis could not be cultured at the time of relapse are most interesting. Again, no significant toxic effects were noted.

COMMENT

In this era of antibiotic and chemotherapeutic agents, the fungous diseases have become increasingly important. In all probability their relative resistance to modern methods of treatment has been a factor in this development. In the past the diagnosis of fungous infections was often academic, but with the development of more effective therapeutic regimens prompt diagnosis is important. The current literature mirrors the greater frequency with which these diseases are being considered and diagnosed. Certainly, the laboratory procedures required for an unequivocal diagnosis of these infections necessitate some degree of training but are not overly difficult, time consuming, or expensive.

The commonest of the highly fatal mycotic infections is actinomycosis.[2] The exact incidence of this condition is not known, but it cannot be extremely rare, since 10 cases were observed at the John Gaston Hospital and the University of Tennessee College of Medicine in the past three years. It would appear that actinomycosis is frequently not considered and so is often misdiagnosed. In case 1, the patient had been observed by numerous physicians for three years and yet fungous diseases had not been investigated. Similarly, case 3 was regarded as a chronic pyogenic infection. These two cases emphasize the fact that actinomycosis should be considered in the differential diagnosis of all subacute and chronic inflammatory processes in which the etiological agent is not readily obvious; especially is this indicated if the cervicofacial area is involved and if there is a preceding history of trauma. Undoubtedly numerous patients with actinomycosis have been diagnosed as having tuberculosis; frequently microscopic and bacteriological procedures are required to differentiate these conditions. In case 2 both infections were present.

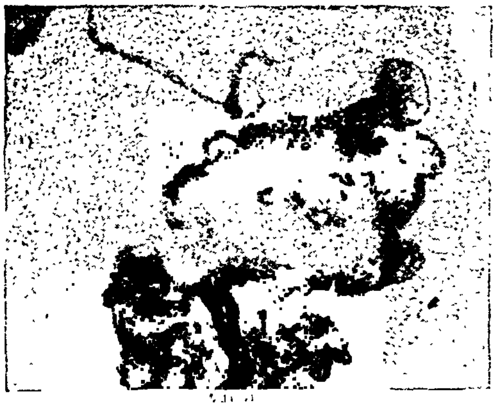

Fig. 2.—Sulfur-like granule in case 3.

Surgical procedures and radiation therapy have proved to be of value in localized actinomycosis.[8] More recently the sulfonamides, penicillin, and aureomycin have been shown to be effective in both localized and disseminated forms of this disease.[9] Even so, treatment has remained prolonged, expensive, and far from uniformly successful.

In view of the reported value of isoniazid in tuberculosis (a disease in many ways similar to actinomycosis), this agent was investigated in the treatment of actinomycosis.[7] In vitro studies with three strains of Actinomyces bovis demonstrated a definite inhibitory effect by isoniazid. Similarly, in vivo results with this agent were most encouraging. It appears that much larger doses must be administered in actinomycotic infections than are usually employed in tuberculosis; instead of 2 to 4 mg. per kilogram of body weight per day, 10 to 18 mg. per kilogram per day seems to be indicated. If smaller amounts of medicaments are administered, improvement is very gradual and recurrence is likely. This is illustrated by case 3 and the initial treatment of case 1. With doses up to 18 mg. per kilogram per day, no evidence of significant toxicity was observed over a period of 4 to 10 weeks.

Side-effects consisted of dizziness, tingling in the extremities, anorexia, and nausea. Whether a more prolonged course of therapy would have resulted in increased toxicity is uncertain. Obviously, until more is known concerning isoniazid, patients receiving such dosage should be carefully observed. A review of the current literature suggests that neurological disease, a history of emotional instability or of psychotic episodes, or evidence of serious renal or hepatic disease might contraindicate the use of isoniazid. No patient in the present series received isoniazid until a thorough history and physicial examination had essentially eliminated neurological disease. Likewise, renal and hepatic function were determined prior to treatment. The one therapeutic failure in this study occurred in a patient (case 3) who received only 9.3 mg. per kilogram per day of isoniazid for a period of 28 days (a total of 19.6 gm.). The other two patients received 30 gm. and 33.6 gm. over a period of 67 and 42 days, respectively. It is realized that the follow-up periods in the three cases reported in this study are quite brief and that prolonged observation is necessary; however, the in vitro studies and initial clinical results indicate that isoniazid is of value in the treatment of actinomycosis.

SUMMARY

In vitro studies demonstrated an inhibitory effect by isoniazid (Nydrazid) against three strains of Actinomyces bovis. Encouraging clinical results were obtained in three cases of cervicofacial actinomycosis. No significant toxic effects were observed. A definite evaluation of the effectiveness of isoniazid in the treatment of localized and disseminated actinomycosis will require the prolonged observation of a large series of cases.

CONTROLLED ERGOMETRIC STUDIES OF EFFECT OF HEPARIN ON INTERMITTENT CLAUDICATION

Eugene P. Simon, M.D.
and
Irving S. Wright, M.D., New York

Clinical experience has demonstrated the need for an accurate method for the determination of claudication time.* The subjective report of the patient with intermittent claudication is frequently extremely variable and has proved unsatisfactory for the evaluation of therapy in occlusive vascular disease. The time of onset of claudication pain may be influenced by the rate of walking,[1] the gradient of the incline on which the walking is done, and psychological factors. Patients frequently report variations in claudication time apparently related to environmental temperature or humidity.

Interest in this subject was renewed following the report of Graham and co-workers,[2] later confirmed by Engelberg,[3] suggesting that intermittent heparin administration resulted in relief of angina pectoris in patients with coronary arteriosclerosis. Recognizing the difficulty in evaluating the effect of any treatment for angina as well as the basic similarity of angina and claudication,[4] we have endeavored to determine objectively whether heparin would alter the development of intermittent claudication in patients with arteriosclerosis of the lower extremities. More recently Engelberg and Massell [5] have reported marked improvement in level walking tolerance in 8 out of 10 patients with peripheral arteriosclerosis receiving heparin therapy. In this study there was no control period of placebo therapy and no mention is made of the method used to maintain a constant rate of walking during the various tests.

Other studies concerned with the measurement of intermittent claudication have utilized a variety of types of apparatus, including a foot treadle ergometer [1] and a bicycle ergometer.[6] With the latter techniques the rate of exercise was regulated by a metronome. Rhythmic faradic stimulation of the leg muscles has been used to control the rate and strength of muscle contraction.[7] It seemed advisable to eliminate voluntary control of the rate of muscular contraction but to allow the subject to utilize his normal gait. An electrically driven treadmill ergometer was therefore constructed.

METHOD

A treadmill consisting of a 14 in. wide endless rubberized canvas belt on wooden rollers was activated by a ¼ h. p. alternating current electric motor. These two units were coupled by means of a variable speed belt drive, a fixed ratio reduction gear drive, and a chain drive, which transmitted the power to rollers at both ends of the treadmill. Both the treadmill and the power unit were mounted on a stable platform, the surface of the treadmill being level. On either side of the treadmill,

Aided by grants from the Kress Foundation, the Albert and Mary Lasker Foundation, the Lillia Babbit Hyde Foundation, and the Hampil Foundation.

* For this study the definition of claudication time was that point at which walking was no longer possible because of the severity of cramps, aching, or extreme fatigue in the muscles of one or both legs.

separated by 24 in., guide bars were placed at a level convenient to the hands of the subject being tested. Along these guide bars sliding tubes were placed and connected to pull switches in such a fashion that a short backwards pull by either of the subject's hands would either start or stop the motor (fig. 1). The speed of the treadmill surface could be varied from 70 to 210 ft. per minute. When the variable speed drive was locked, the speed, as determined by mechanical counter and stop watch, was found not to vary to any significant degree under loads ranging from none to 250 lb. (113.4 kg.), or with ordinary variations in line voltage. The apparatus was placed in a quiet examining room in such a way that the test subject faced a blank wall while walking.

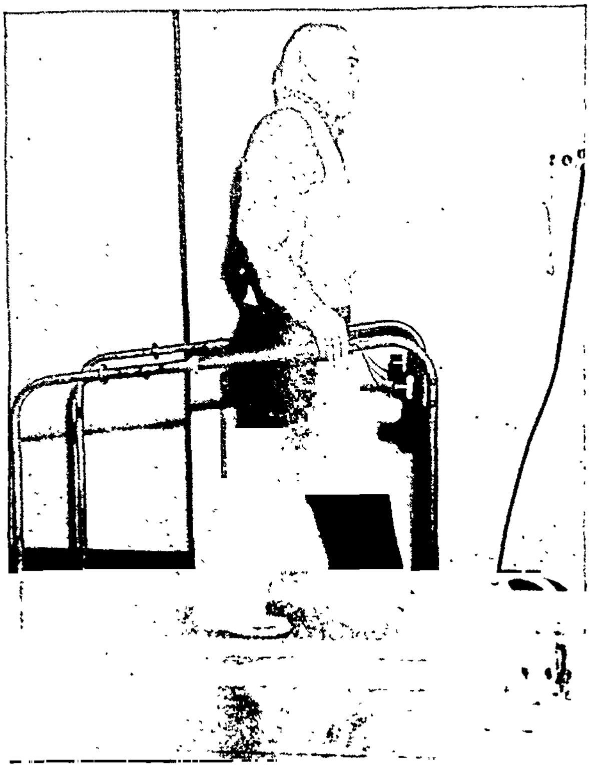

Fig. 1.—Subject walking on treadmill ergometer. The right hand is in position to activate the pull switch.

The subject was tested at approximately the same hour (usually 9 a. m.) of the same day of each week. Rarely two or three weeks passed between tests. After sitting quietly for 30 minutes, he was told to mount the treadmill, start it himself, and walk as long as he could. In these studies the speed of the machine was set at 140 ft. per minute, at which rate intermittent claudication always developed. When the subject could no longer walk because of claudication, he stopped the machine by pulling the switch at his side. Placebo or heparin was then injected intravenously, and after resting 30 minutes the patient repeated the procedure. The average of the two claudication times was recorded. Except for one observer, the subject was alone in the room. The subject could not see the observer from his walking position, and no conversation was carried on. Time was measured with a stop watch by the observer who did not know which medication was being given, in most instances. The patients were not given information about medication or claudication time. Wrist watches were removed, but one subject (case 6) counted his steps. Medication, given intravenously twice weekly, consisted of isotonic sodium chloride solution, 2 ml., or heparin sodium solution (Liquaemin †), 50 mg. of heparin sodium per milliliter of sterile isotonic solution, 2 ml. The subjects all received two injections each week, whether or not they were tested during that week. All subjects had stopped smoking at least two months before this study began. No medication other than heparin or placebo was given.

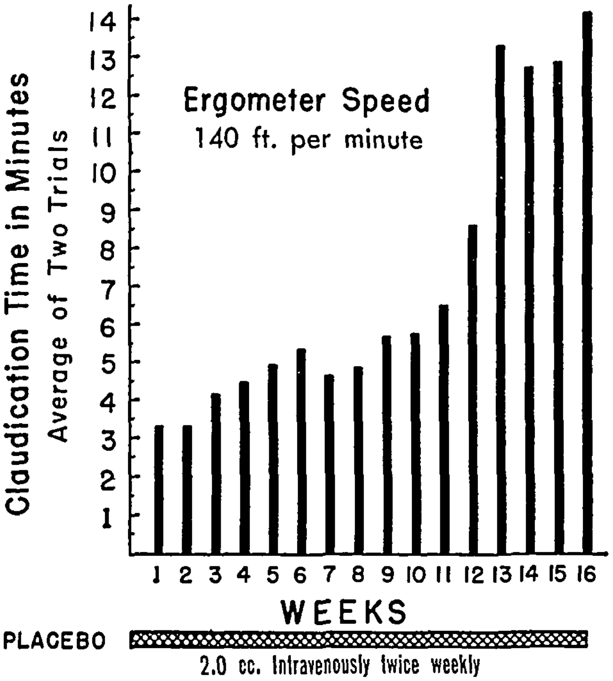

Fig. 2.—Progressive improvement of claudication times of subject in case 1 while receiving only placebo therapy.

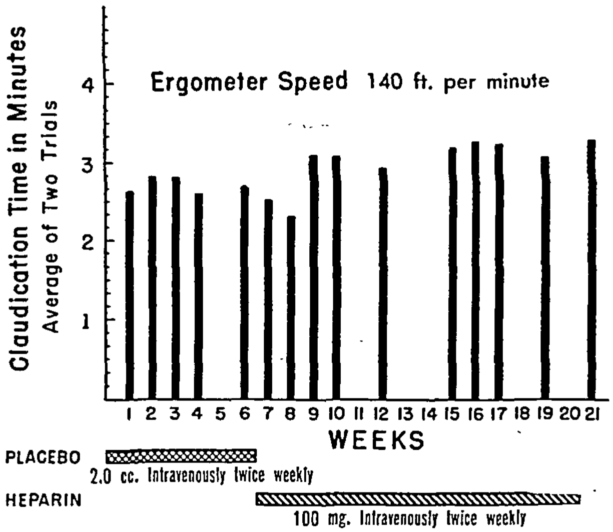

Fig. 3.—Absence of improvement of claudication times of subject in case 2 during 6½ weeks of placebo therapy and 14½ weeks of intermittent heparin therapy.

The subjects reported in this study were chosen from among the outpatients at the New York Hospital Medical

Vascular Clinic. Although the total number, six, is small, it should be noted that each was followed in this study for periods of from 12 to 24 weeks. Data on other subjects on whom observations were made are not included in this report because of inability or unwillingness to come to the hospital twice weekly for a minimum of 12 weeks, a period arbitrarily chosen for inclusion in this report. Two of these latter subjects improved so rapidly while receiving placebo that they felt no further need for the frequent visits. All subjects included in this report complained of intermittent claudication after walking short distances. All showed evidences of arterial insufficiency of one or both lower extremities, as manifested by diminished or absent arterial pulsations and oscillometric readings, pallor on elevation, rubor on dependency, and reduced skin temperature. In all cases the diagnosis of arteriosclerosis obliterans was determined by the usual clinical criteria,[1] in some cases confirmed by radiographic and angiographic examination. Patients were excluded if there was evidence or suspicion of thromboangiitis obliterans or embolic arterial occlusion, as were those with skin ulceration, orthopedic or neurological conditions, or cardiac decompensation.

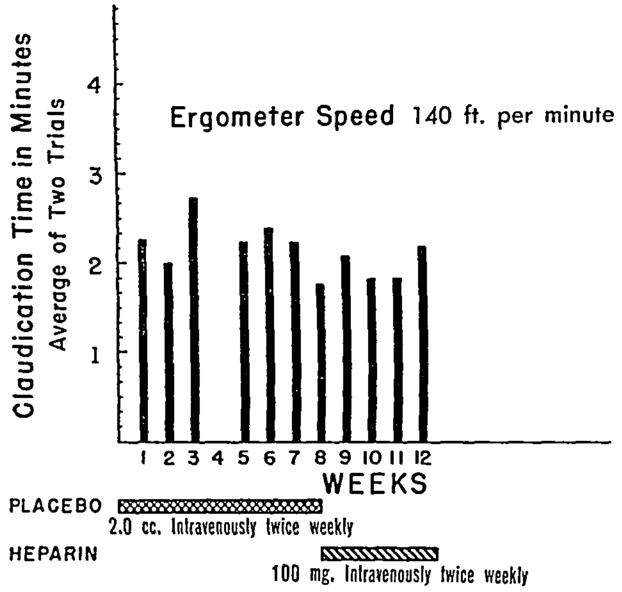

Fig. 4.—Absence of improvement of claudication times of subject in case 3 during eight weeks of placebo therapy and four weeks of intermittent heparin therapy.

REPORT OF CASES

Case 1.—A 51-year-old white man complained for 15 months of bilateral intermittent claudication after walking 500 ft. Examination revealed absent posterior tibial and dorsalis pedis pulsations and absent oscillometric pulsations at the ankles and feet. On placebo therapy alone he showed striking prolongation of his claudication times (fig. 2) and reported corresponding improvement in his ordinary walking. Oscillometric pulsations appeared at the ankles and gradually increased to about one-half the normal minimum. This study began in October and ended in January.

Case 2.—A 52-year-old white man complained for five years of bilateral intermittent claudication after walking 300 ft. Examination showed only feeble femoral pulsations, markedly diminished oscillometric pulsations below the knees, and absent oscillometric pulsations at the ankles and feet. Three years earlier radiographic and angiographic studies had demonstrated calcified and almost completely occluded terminal aorta and iliac vessels. A bilateral lumbar sympathectomy had been done three years prior to the present study, but there was no improvement. During 22 weeks of placebo and heparin therapy there was moderate subjective improvement, with no significant alteration in the signs of occlusive arterial disease or claudication time (fig. 3). This study began in March and ended in August.

Case 3.—A 51-year-old white woman complained for four years of severe bilateral intermittent claudication after walking 300 ft. Femoral pulsations were weak, with absent oscillometric pulsations at the ankles and feet. Radiographic and angiographic studies two years earlier had revealed calcified and partially occluded iliac vessels. During 12 weeks of placebo and heparin therapy there was no significant change in the signs of occlusive arterial disease or in the claudication time, but the patient complained of increasingly severe limitation of ordinary walking (fig. 4). She abandoned the study because of failure to improve. This study began in March and ended in June.

Case 4.—A 63-year-old white man complained for one year of bilateral intermittent claudication after walking 400 ft. Examination showed absent posterior tibial and dorsalis pedis pulses. Oscillometric readings were markedly diminished at the ankles and absent in the feet. During both placebo and heparin therapy moderate subjective improvement was reported. There was no significant change in the signs of occlusive arterial disease, nor was there any consistent improvement in the claudication times (fig. 5). This study began in April and ended in September.

Case 5.—A 56-year-old white woman complained for three months of intermittent claudication in the right leg after walking 500 ft. Examination revealed absent posterior tibial and dorsalis pedis pulsations on the right. Oscillometric pulsations were markedly diminished at the right ankle and absent in the right foot. Radiographic studies showed calcification of peripheral blood vessels. Gradual moderate subjective improvement was noted during both placebo and heparin therapy. Oscillometric pulsations improved slightly. Claudication times were more often longer during heparin therapy, but the longest was not significantly longer than the longest achieved during placebo therapy (fig. 6). This study began in March and ended in August.

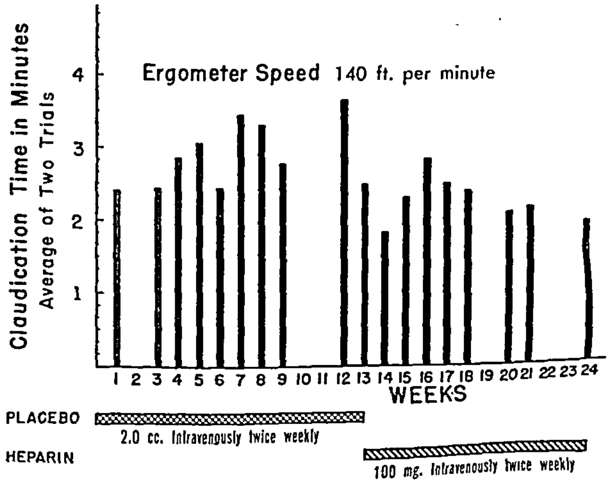

Fig. 5.—Absence of improvement of claudication times of subject in case 4 during 13 weeks of placebo therapy and 11 weeks of intermittent heparin therapy.

Case 6.—A 69-year-old white man complained for two years of bilateral intermittent claudication after walking 500 ft. Examination showed absent posterior tibial and dorsalis pedis pulses. Oscillometric pulsations were markedly diminished below the knees and at the ankles and were absent in the feet. During the period of heparin therapy a gradual subjective improvement was reported, claudication times were longer (fig. 7), and oscillometric readings were improved. During the second period of placebo therapy further improvement, greater in degree, occurred. These findings were interpreted as indication that the improvement and heparin therapy were probably coincidental rather than related. This study began in September and ended in January.

COMMENT

The precise analysis and control of the multiple variables that determine the time of onset of muscle pain on exercise by subjects with peripheral arteriosclerosis is beyond the scope of currently available methods of investigation. Although the mechanical aspects of the exercise procedure may be carefully controlled, with minimization of environmental and psychological variables, variability within certain limits must be considered a characteristic finding in studies on intermittent claudication. Despite this limitation, it has been found feasible and desirable to utilize an electrically driven and controlled treadmill ergometer in long-term studies of intermittent claudication.

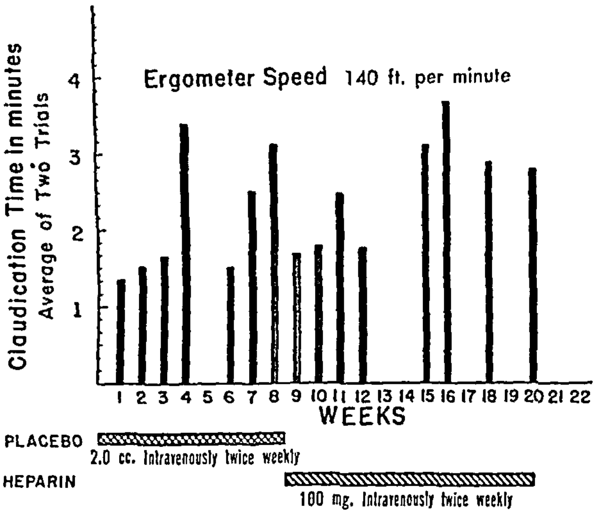

Fig. 6.—Absence of improvement of claudication times of subject in case 5 during 8½ weeks of placebo therapy and 11½ weeks of intermittent heparin therapy.

Important degrees of improvement occurred in the exercise tolerance of patients receiving a placebo (cases 1 and 6). This may be due to a spontaneous occurrence in the course of the arteriosclerotic disease process. It is also possible that collateral circulation has been improved in these subjects in response to repeated tolerance tests with the consequent muscle anoxia. This phenomenon has been postulated as a basic mechanism in the development in intercoronary collateral circulation.[8] In view of the techniques used and the objective evidences of improved peripheral circulation, the psychological effect of treatment was not considered to be a major factor responsible for longer claudication times in these cases.

In other subjects (cases 2 and 4) moderate subjective improvement was reported during placebo and heparin therapy, although there was no significant change in the physical signs of arterial insufficiency, or in the claudication time. In one subject (case 5) moderate subjective and slight oscillometric improvement occurred during placebo and heparin therapy without significant improvement in claudication times. One subject (case 3) experienced increasingly severe subjective symptoms without alteration in physical signs or claudication times.

In none of the five subjects who received intermittent heparin therapy was there a relation of any alteration in subjective symptoms, physical findings, or claudication times to the administration of heparin. The findings of Engelberg and Massell[6] could not be confirmed, probably due to the use of different techniques of study. Similarly, Russek and co-workers[9] have been unable to obtain improvement in anginal symptoms with heparin administration, a finding which coincides with our own.[10] Carefully controlled studies are essential in the evaluation of agents in the treatment of vascular disease. Spontaneous variations in the subjective and objective manifestations of disease, as well as the effects of other coincidental or therapeutic measures, have frequently been mistaken for a specific therapeutic effect of the drug under investigation.

SUMMARY AND CONCLUSIONS

A method for the determination of claudication time in subjects with occlusive arterial disease, utilizing an electrically driven treadmill ergometer, is described. The clinical histories, physical findings, and claudication time records of six arteriosclerotic subjects, with observation periods ranging from 12 to 24 weeks, are presented. The variability of claudication times in the same patient in a controlled situation is illustrated. The potential for significant improvement in the manifestations of arterial

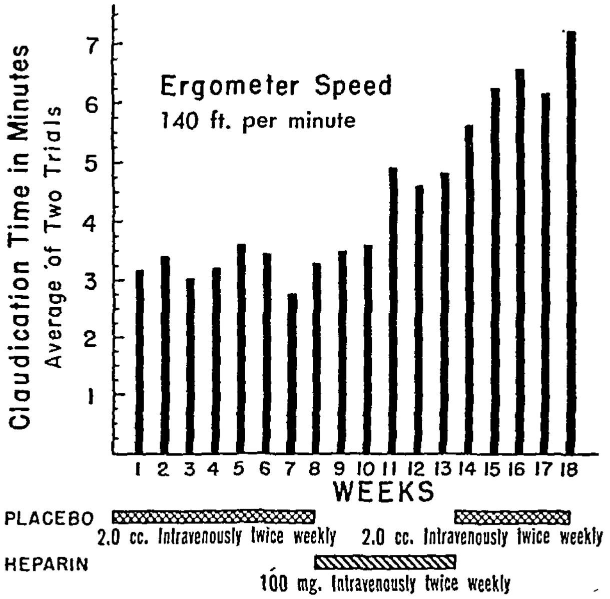

Fig. 7.—Improvement of claudication times of subject in case 6 during five and one-half weeks of intermittent heparin therapy and four and one-half weeks of placebo therapy.

disease without treatment, other than abstinence from tobacco, is emphasized. In five arteriosclerotic patients receiving intermittent heparin therapy for periods ranging from 4 to 14 weeks no beneficial effects were observed. Careful control of studies designed to evaluate therapeutic measures for occlusive arterial disease is recommended.

CLINICAL NOTES

RUPTURE OF A THORACIC ANEURYSM INTO THE STOMACH

William F. Renner, M.D.
and
Joseph Sindelar, M.D., Baltimore

Rupture of an aneurysm of the thoracic aorta into the esophagus is a recognized clinical and pathological entity. Rupture of an aneurysm of the abdominal aorta into the stomach has been reported in at least seven cases. A search of the literature has revealed no report of rupture of a thoracic aneurysm into the stomach. The case we report is a clear example of such an occurrence. Of particular interest is the fact that this case presented symptoms and signs that may be considered diagnostic of rupture of a thoracic aneurysm into the stomach.

REPORT OF A CASE

The patient was a Negro man 61 years of age. His history and that of his family supplied no pertinent information. At noon on the day of admission, severe pain beneath the sternum and in the upper epigastrium developed in the patient. The pain was accompanied by nausea. When the patient arrived in the accident room one hour after the onset of symptoms, he was in shock, with a blood pressure of 60/0 mm. Hg. The skin was cold and clammy. Profuse perspiration was present. A loud systolic murmur was heard over the entire precordium. During the course of the initial examination in the accident room, it was noted that a rapidly expanding tumor mass was developing in the epigastric area. Over the period of a few minutes, the mass was observed to have increased in size. The mass clearly conformed to the outline of the stomach. Shortly after his arrival in the accident room, the patient began to vomit large amounts of bright red blood in a projectile fashion. The patient failed to respond to efforts made to combat anemia and shock, and he died 17 hours after the onset of symptoms.

At autopsy, two saccular aneurysms were found that were both located 3 cm. below the termination of the arch of the aorta (fig. 1*A*). Each aneurysm measured approximately 3 by 2 cm. One was thin walled but intact and had eroded the anterior surface of the fourth thoracic vertebra to about one-third of its depth. The second aneurysm had ruptured into the mediastinum and had dissected its way along the esophagus (fig. 1*B*). At no point had the hemorrhage penetrated the esophageal mucosa. The hematoma was traced down the esophagus to the stomach where it was found to terminate in an irregular opening in the anterior wall of the stomach 3 cm. below the cardiac sphincter (fig. 2). The stomach and duodenum were distended with blood.

Microscopic section of the esophagus showed extensive hemorrhage without penetration of the mucosa. Sections of the aorta were considered typical of syphilitic aortitis. Sections of the mucosal rent in the stomach showed normal gastric mucosa interrupted abruptly by a blood clot that extended through all layers of the stomach.

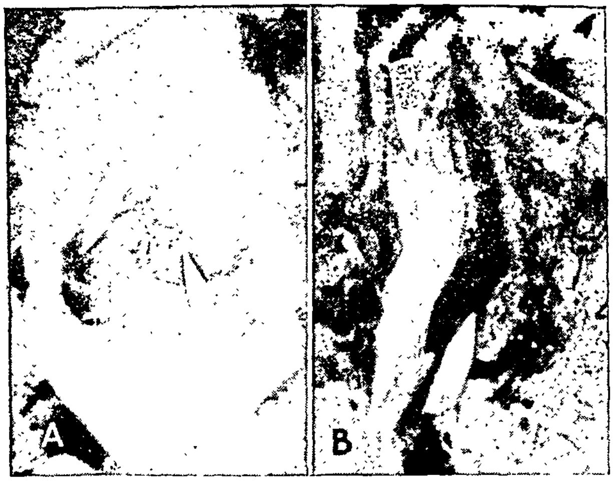

Fig. 1.—*A*, two aneurysms are located in the descending aorta 3 cm. below the termination of the arch of the aorta. The aneurysm to right perforated. *B*, The upper arrow points to the descending aorta; the lower, to the hematoma that dissected its way along the esophagus.

COMMENT

Lemann has made a study of 592 cases in which aneurysms of the thoracic aorta ruptured.[1] In 50, rupture into the esophagus occurred; in none was the rupture into the stomach. Rupture of an abdominal aneurysm into the gastrointestinal tract is rare. In a review of the literature in 1951 by Hirst and Affeldt, only 43 such cases could be found.[2] They added eight cases from a study of 16,633 autopsies. When an abdominal aneurysm does rupture into the gastrointestinal tract, the usual site is the third portion of the duodenum, probably because of its relative fixation. Of the total of 51 cases in which an abdominal aneurysm ruptured into the gastrointestinal tract, only seven ruptured into the stomach.

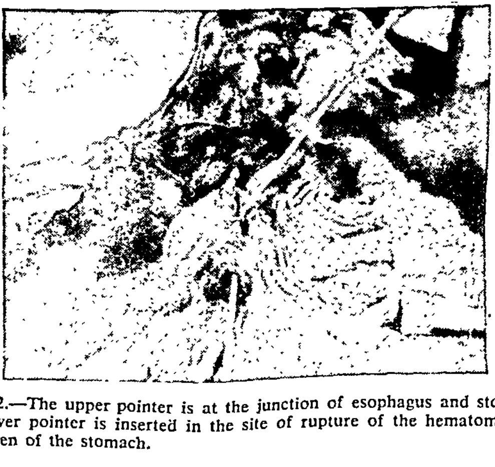

Fig. 2.—The upper pointer is at the junction of esophagus and stomach. The lower pointer is inserted in the site of rupture of the hematoma into the lumen of the stomach.

The occurrence of sudden, severe substernal pain accompanied by shock in an elderly patient invariably brings to the mind of the physician a consideration of acute myocardial infarction, and such was true in the case we report. The progression of events, however,

[2] Hirst, A. E., Jr., and Affeldt, J.: Abdominal Aortic Aneurysm with Rupture Into the Duodenum: Report of Eight Cases, Gastroenterology 17: 504, 1951.

quickly made this diagnosis untenable. The severe substernal pain correctly indicated the chest as the primary location of the trouble. The vomiting of large amounts of bright red blood indicated a link between the gastrointestinal tract and a blood vessel of considerable size. The rapidly expanding, firm epigastric mass, with the outline of the stomach in an abdomen that otherwise was soft and flat, could only be caused by a large amount of blood gushing into the stomach under pressure. It is difficult to conceive of any other condition than the one found at autopsy that could have given rise to this combination of symptoms and signs. It might be thought that rupture of an aneurysm into the esophagus could give an identical clinical syndrome; however, in the instance of rupture into the esophagus, the action of the cardiac sphincter does not favor retention of blood under pressure in the stomach and consequent distention as is true of rupture into the stomach. In the few detailed case reports of rupture of an aortic aneurysm into the esophagus, that we have been able to find, no mention is made of enlargement of the stomach.[3] Rupture of an aneurysm of the gastric artery is a condition in which blood is introduced into the stomach rapidly and under pressure; however, this condition would not be expected to cause chest pain. Moreover, in three reported cases of rupture of an aneurysm of the gastric artery into the stomach, no gastric enlargement was noted.[4] The occurrence of severe substernal pain of sudden onset, profuse hematemesis, and a rapidly expanding epigastric tumor, conforming to the gross anatomy of the stomach, may, therefore, be considered a diagnostic triad for rupture of a thoracic aneurysm into the stomach.

SUMMARY

Rupture of a syphilitic aneurysm of the thoracic aorta into the stomach is reported.

CONGENITAL HEMOLYTIC ANEMIA IN NEGRO BROTHERS

REPORT OF TWO CASES

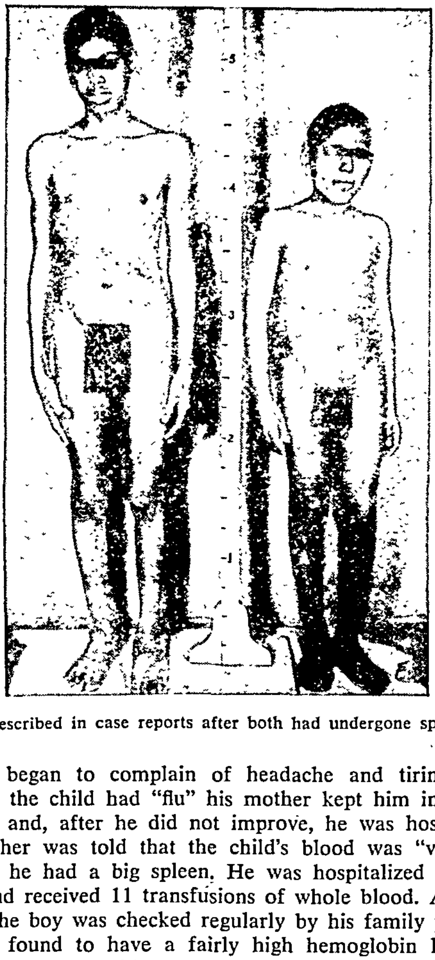
Robert Irby, M.D., Richmond, Va.

Prior to 1944, there had been only one recorded instance of congenital hemolytic anemia in the Negro race. That was the case of a Negro woman of "undoubtedly mixed blood" cited by Wintrobe in 1942.[1] In 1945, Scherer and Cecil[2] reported the disease in a 14-year-old Negro girl, and Smith and Drake[3] presented a 22-year-old Negro man. Both the man and the girl underwent splenectomy with good results. A review of the literature reveals that 15 other cases have been reported in the Negro race by various clinicians. In September, 1950, Butterworth, Kracke, and Riser[4] reported two more cases, a woman and her great aunt. To date, a total of 18 cases in 9 families have been reported. Only 5 of the 18 patients had splenectomy, and it is interesting to note that only 4 of those 18 persons were Negro men.

The purpose of this paper is to present two additional cases of congenital hemolytic anemia in Negro brothers, both of whom were treated by splenectomy. Both of the patients in this report showed strong Negroid characteristics, as did their mother. She, however, in contrast to her sons failed to show any enlargement of the spleen, evidence of anemia or reticulocytosis, or increase in blood cell fragility, serum bilirubin, or microspherocytosis

REPORT OF CASES

Case 1.—A 13-year-old Negro boy was admitted to the hospital on Jan. 15, 1951, because of "big spleen and anemia." The patient had been well until the summer of 1949, at which time he began to complain of headache and tiring easily. Thinking the child had "flu" his mother kept him in bed for 10 days, and, after he did not improve, he was hospitalized. The mother was told that the child's blood was "very low" and that he had a big spleen. He was hospitalized for eight weeks and received 11 transfusions of whole blood. After discharge, the boy was checked regularly by his family physician and was found to have a fairly high hemoglobin level and erythrocyte count, with no evidence of jaundice. There had been no history of jaundice, black urine, hematemesis, black or clay-colored stools, or malaria. Family history failed to



Brothers described in case reports after both had undergone splenectomy.

From the Department of Medicine, Medical College of Virginia.

Drs. G. Watson James III, James O. Burke, and Herbert C. Lee, all of the Medical College of Virginia Hospital, assisted in the preparation of this paper.

reveal any evidence of jaundice or anemia other than in the patient's brother who was admitted to the hospital the same day. The patient had a tonsillectomy when he was 6, with no postoperative complications.

Physical examination revealed a somewhat thin boy in no distress. There was no suggestion of icterus or anemia. The heart and lungs were normal except for a soft blowing systolic murmur heard over the apex. The spleen was felt 5 cm. below the costal margin and was not tender. The liver edge was felt just below the costal margin on the right side. On the fourth hospital day, a slight fever and some icterus developed. It was thought that a crisis was impending, and there was a drop in the reticulocyte count, but the fever subsided and operation was carried out as planned. The laboratory findings are recorded in the table. The diagnosis of congenital hemolytic anemia was made, and splenectomy was performed on the seventh hospital day. The spleen was removed through a left subcostal incision; it measured 15.5 by 11.5 by 4 cm. The pathologist reported that there was splenomegaly probably due to congenital hemolytic jaundice. The boy recovered uneventfully and was discharged *on the 11th* postoperative day.

Laboratory Data on Brothers in Cases 1 and 2 Before and After Splenectomy and Data on Patients' Mother

	Case 1		Case 2		
	Before Splenectomy	After Splenectomy	Before Splenectomy	After Splenectomy	Mother
Hemoglobin, gm. per 100 cc.	14.4	14.4	12.2	15.2	15.6
Red blood cells, per cubic millimeter	4,400,000	4,500,000	3,860,000	4,950,000	5,040,000
White blood cells, per cubic millimeter	6,200	13,200	7,600	8,800	6,000
Reticulocyte count, %	13	4	15	0.2	1.8
Platelet count	168,000	1,098,000	224,000	535,000	....
Sickle cell prep	Negative	....	Negative	....	....
Bleeding time	1'25"	....	1'50"	....	....
Clotting time	4'30"	....	4'25"	....	....
Serum bilirubin, mg. per 100 cc.					
1 min.	0.4	0.2	0.4	0.2	0.2
Total	2.0	0.6	2.4	0.6	0.8
Urine urobilinogen, mg. per day	5.06	0.606	0.609	0.360	....
Fecal urobilinogen, mg. per day	900	198	869 *	710 *	....
Red blood cell fragility, % in saline	0.7 to 0.44	0.7 to 0.44	0.7 to 0.44	0.7 to 0.28	0.56 to 0.28
Microspherocytosis	+ †	+	+	+	− ‡
Sternal marrow	Erythroid hyperplasia	....	Erythroid hyperplasia	....	....
Coombs test	Negative	....	Negative	....	....

* Because in case 2 only 5 gm. feces were excreted in 48 hr. preoperatively and 82 gm. postoperatively, these values were calculated as mg. per 100 gm. of feces.

† Present.

‡ Not present.

CASE 2.—An 11-year-old Negro boy was admitted to the hospital on Jan. 15, 1951, because of "anemia and a big spleen." This patient had a history somewhat similar to his older brother's (case 1). Systems review disclosed that he frequently took laxatives for "sluggish bowels." Except for some inability to keep up with his childhood activities, the boy was well until the summer of 1949. Two weeks after his brother had entered a hospital because of "flu," this boy began to complain of weakness, headache, and general malaise. He was found to have anemia and an enlarged spleen and was given 10 whole blood transfusions over an eight week period. After that he felt well until the summer of 1950, when weakness and a low grade fever developed. When jaundice appeared, he was taken to the hospital where he received an additional pint (0.5 liter) of blood. In contrast to his brother, this patient had recently had dark urine. He had had a tonsillectomy at the age of four without complications.

Physical examination revealed a rather chubby-faced boy, with slightly pale conjunctivas and mucous membranes but no visible icterus. The heart and lungs were clear. The spleen was felt 8 cm. below the costal margin on the left side and was much larger and firmer than that of the brother. The liver edge was not felt. The laboratory findings are shown in the table. Splenectomy was performed. The spleen weighed 360 gm. and measured 12 by 14.5 by 4 cm. The pathologist reported that splenomegaly was probably due to congenital hemolytic jaundice. The child had an uneventful recovery and was discharged on the 11th postoperative day (see figure).

COMMENT

Congenital hemolytic anemia in the Negro race was a rare entity until 1944, but, in the last six years, it has become apparent that this disease in the Negro race is recognized more frequently. Because the disease may be benign in itself, splenectomy has been refused in many cases in the past. Only 4 of the 18 previously reported patients were Negro men.

After the diagnosis of congenital hemolytic anemia was made in the two patients described here, splenectomy was performed in both and was followed by the disappearance of evidence of increased hemolysis and reticulocytosis, although microspherocytosis and increased fragility remained. The mother of the patients was found to have no evidence of jaundice, splenomegaly, or anemia.

In case 2, the fecal urobilinogen was not diminished on the 10th day after splenectomy. Both the preoperative and postoperative determinations were measured on small samples of feces, and, therefore, the daily excretion could not be determined. Whether excessive pigment excretion was the result of gastrointestinal stasis or of continuing hemolysis is difficult to appraise. With the history of sluggish bowel movements in case 2 and with the marked postoperative diminution in the reticulocyte count, it is suspected that intestinal stasis, as well as the use of unavoidably small samples for analysis led to these results.

SUMMARY

Two cases of congenital hemolytic anemia in Negro brothers are presented, with data illustrating the beneficial effects of splenectomy. This report makes a total of 20 patients in 10 families now recorded in the literature. Six of the 20 patients are males.

Introduction

This 53rd annual report on medical education in the United States and Canada, compiled by the Council on Medical Education and Hospitals, covers the period from July 1, 1952, to June 30, 1953. Included in it are data, derived from official sources, concerning medical schools, students, graduates, the relationship of medical education to national defense, and other topics of importance. This annual compilation is an important reference source for many individuals and organizations that are concerned with medical education. The Council is grateful to the many persons who have contributed to the development of the report and wishes particularly to thank the administrative officers of the medical schools who, at the expense of much time and effort, have provided most of the basic information upon which the report is based.

Publication of the final report of the Survey of Medical Education [1] was an event of major importance this year. Data published annually in this report have reflected financial, organizational, and other problems of the medical schools and have reported the planning and experimentation of the schools to meet these problems. All of those concerned with medical education will therefore welcome an opportunity to review their own problems and plans in light of the careful analyses and recommendations, covering all phases of our medical schools' activities, which are contained in the survey report.

The financial support of medical education continues as a problem of immediate and pressing importance. As is noted in the section on financial support, significant increases in the annual income of the schools has been offset to a considerable degree by expansion in the activities of the schools and by inflationary increases in costs. Although tremendous expenditures have been made by the schools in recent years for the construction of new facilities, a considerable proportion of these expenditures have been for clinical facilities and many schools are still particularly in need of funds for the improvement of their basic science facilities. All schools have not participated equally in the increased support that has been made available, and several have had so little success as to place their continued existence in doubt. However, there are new medical schools in the process of development that seem assured of substantial and continuing support.

Among the many curriculum experiments that have been initiated by the schools, the one that will attract the greatest interest is that being carried on at Western Reserve University. This program is organized completely along the lines of correlative, multi-disciplined teaching and discards the traditional division of teaching by special basic science and clinical disciplines. The first class to receive instruction under this plan was enrolled in 1952-1953. A brief description of the program is contained in the section on major developments, and a panel discussion of it, by members of the Western Reserve faculty, will be found in the Proceedings of the Annual Congress on Medical Education and Licensure for 1953.

Another event that will attract attention is the leveling off in student enrollment. Both last year's freshman class and the expected freshman class for 1953-1954 are slightly smaller than the entering class of 1951-1952. This may be regarded as a temporary readjustment following a period of rapid expansion, and further increases in enrollments are expected when expansion programs now under construction are completed and when new schools now being planned are in full operation.

Certainly more important than this temporary leveling off in the expansion of enrollments of undergraduate medical students is the absence of any increase in the number of graduate students in the basic medical sciences. Continuing failure to increase the supply of scientists in these already undermanned areas will have a serious effect not only upon research programs but upon the quality of the basic educational programs in medicine.

---

1. Deitrick, J. E., and Berson, R. C.: Medical Schools in the United States at Mid-Century, New York, McGraw-Hill Book Co., 1953.

This year, for the first time, information is presented on the scholarship and loan funds available to undergraduate students of medicine. These data make it clear that while some schools have relatively large sums for such purposes, a number of other schools can offer little such help to their students.

At this writing, it is too early to tell what the full impact of the Korean truce on the medical schools will be. At least, for a short term, military calls for medical officers may decrease somewhat and the drain on medical faculties may be eased. Nevertheless, a significant degree of mobilization is certain to continue and the need for preparation of medical students for military and civil defense services will persist. Long range plans for medical education for national defense have been under development by the Joint Committee on Medical Education in Time of National Emergency since June of 1950. The section on Medical Education and National Defense reports the initiation, by the Subcommittee on Medical Education for National Defense, of a new experimental program to prepare undergraduate students for their roles in military service and civil defense.

Survey of Medical Education

Previous Educational Numbers have carried brief progress reports of the Survey of Medical Education, which was organized in 1947 under the joint sponsorship of the Council on Medical Education and Hospitals and the Association of American Medical Colleges. It was financed by the American Medical Association, the Association of American Medical Colleges, and a grant from the W. K. Kellogg Foundation. During the past year the final report of the survey was completed and published in book form.[1] The report is based on the findings of detailed visits by the staff of the survey to 41 medical schools, on additional information provided in response to questionnaires by all the medical schools, and on data compiled over the years by the Council on Medical Education and Hospitals and the Association of American Medical Colleges.

Rather than concentrate its attention primarily on the teaching programs of the medical schools, the survey, as explained by its chairman, Alan Valentine [2] in his foreword to the report, early became convinced that its most important contribution lay in the direction of analyzing and defining the current position of the medical schools as social and educational instruments. Thus, a considerable proportion of the report deals with an analysis of the activities of a medical school, the finances of the medical schools and the administrative organization, policies, and practices of the schools.

The report presents the most convincing evidence yet compiled demonstrating the complexity and broad scope of the activities and responsibilities of a modern medical school. It analyzes in detail the activities of typical schools in the three major fields of education, research, and service. This analysis is significant in the light that it sheds on the nature and reasons for the high cost of maintaining a modern medical school. Actually, the report estimates that despite recent substantial increases in the budgets of the medical schools, the schools in terms of purchasing power of the dollar are spending only slightly more on instruction now than they were just before World War II. An analysis of the schools' expenditures indicates that during the decade 1940-1950, primary emphasis was on expansion of research activities. Noting this and other shifts of emphasis, the report urges that the medical schools define precisely the activities that are to be included in medical education, that the schools revise their accounting practices in accord with such a definition, and that the schools maintain a balance in their activities that will preserve their basic function as educational institutions.

These recommendations point up the growing realization among many medical educators that the solution of the financial problem of the medical schools lies as much in reappraising the uses to which available funds are being put as it does in securing additional funds even though there is no question that the total programs of many schools require more adequate support.

It may be commented here that it is doubtful if better cost accounting alone will solve any major problems of inadequate support. Even though it may be shown, as it is in the report of the survey, that university funds assigned to a medical school are used to support the teaching of large numbers of students in other departments, the demonstration of this fact does not increase the total amount of money available to a university for its total educational program. On the other hand, such improved accounting should give the university additional arguments to support its efforts to secure more funds for its medical school and should help to relieve the medical school of possible embarrassment resulting from the fact that its costs are usually high relative to those of other departments of a university.

The report of the survey, however, does suggest certain approaches that should result in more actual money being made available to the medical schools for their essential activities. Thus the report strongly urges that medical schools seek more adequate reimbursement of the indirect costs of research when they accept research grants from government agencies or other sources. The report also urges that the hospital costs of indigent patients be borne by the appropriate private and governmental agencies and not by the medical schools from funds that were given for educational purposes. Again, on the side of conserving the resources and energies of the medical schools, the report warns the schools against the dangers inherent in undertaking extensive medical service programs beyond the needs of the schools' instructional programs.

The report reviews in some detail the various relationships that exist between medical schools and their teaching hospitals and points out that medical schools control appointments to the staff in less than half of their teaching hospitals. The difficulties created for the medical schools by this lack of control in the selection of those who do much important teaching are thoroughly examined. The report makes the further disturbing observation that in certain large city and county hospitals, the unsatisfactory position of the medical schools has not improved essentially since Abraham Flexner's critical comments on these same relationships in 1910. The report urges that until the hospitals referred to fulfill the requirements for a teaching hospital, the medical schools should refuse to conduct teaching programs in them. Unfortunately, many of the schools involved in such unsatisfactory relationships have no other hospitals to which they can readily turn.

---

[1] Deitrick, J. E., and Berson, R. C.: Medical Schools in the United States at Mid-Century, New York, McGraw-Hill Book Co., 1953.

[2] The other members of the Survey of Medical Education were Drs. Herman G. Weiskotten, Victor Johnson, and Donald G. Anderson, representing the Council on Medical Education and Hospitals, and Drs. Arthur C. Bachmeyer, Joseph C. Hinsey, and Dean F. Smiley representing the Association of American Medical Colleges. Dr. John E. Deitrick served as director and Dr. Robert C. Berson as associate director of the survey.

The report contains an excellent chapter on the subject of the selection and admission of students to medical school. Emphasizing that the future quality of medical education, research, and service will depend primarily upon the quality of students selected by the medical schools, the report points out that while the schools have expended a great deal of effort in the selection of students, there are a number of ways in which many schools could improve the quality of their work in this area. In general, these schools would benefit by clarifying their policies and criteria for selection, by making more effective use of the information that is available concerning applicants, and by organizing their admissions committees more effectively and giving more adequate financial support to these committees. The report, while decrying discriminatory and restrictive admission practices and policies, makes a strong plea to state authorities and civic groups that they recognize that the intelligent discharge of the admissions function is hampered and not aided by laws and regulations that seek to limit the nature and extent of the personal information that may be made available to a medical school concerning its applicants.

The section of the report dealing with the administrative and departmental organization of the medical schools again calls attention to the complexity of the activities of a modern medical school. It points out the need for fresh thinking in the design of both the over-all administration of the school and the organization of the individual departments of the school.

The chapter of the report dealing with the curriculum is perhaps most noticeable for the critical light it turns on the philosophy and practices of many schools with respect to examinations. The report calls attention to and cites examples of the emphasis many schools place on multiple examinations that tend to dissipate the time and energies of the medical student and to discourage him from developing a mature attitude toward his medical education. This chapter also points to the great dissatisfaction with teaching in outpatient departments that prevails among both students and teachers in the majority of medical schools and analyzes the underlying reasons for this dissatisfaction.

Although many will feel that the portion of the chapter on curriculum dealing with preceptorships and home care programs is overly critical, the weaknesses and abuses of these programs that are reported are real and their recognition and correction are essential if these programs are to have a valid place in medical education.

The final chapter of the report, appropriately entitled "A Summing Up," brings into final sharp focus the more important questions raised in the body of the report: What is medical education? What is a medical school and what are its responsibilities? Should research be the major goal of a medical school and receive the greatest financial support? What is the goal of the medical school in providing medical care?

The report, while not attempting to answer these and other questions with finality makes pointed observations on all of them. It comments that too often a school today is judged by the public by the magnitude of its activities rather than by the quality of its educational program. It discusses the problems created as medical schools have expanded into medical centers and the trend among medical educators to build large empires with increasing influence and control over many areas of health care.

The chapter concludes with a reminder of the essential truth that it is the medical student who should be at the focus of all the medical school's activities and policies and asks what are the effects of the present programs of the schools on the medical student of today. In a brief and vivid answer, it depicts the present program of medical education as encouraging the development of physicians accustomed to living in a protective, institutional environment, whose capacities for independence and leadership remain undeveloped. To guard against this, the report makes a plea for teachers and administrators who have courage and faith in the idea that the quality of medical education will determine the future of medicine in the United States.

Following the main report are six appendices presenting tables and supporting data. Of particular significance and interest is the appendix summarizing student opinions concerning medical education that were elicited at each school visited by the survey. These expressions of student opinion are for the most part mature, well-considered criticisms that merit the careful consideration of all concerned with medical education.

The report is directed not only to medical educators but equally to the general public in the hope that it will provide the public with a better understanding of the modern medical school and its problems. To meet the needs of this group of readers, the report has brought together a great deal of basic information and statistical data concerning the medical schools and their many activities.

Purposely, no schools are singled out by name for praise or censure in the report. Some who read the report many be surprised at the extent to which it is critical of the medical schools; others may feel that it is not sufficiently critical. Little space has been taken in the report to call attention to or praise those features of the schools which deserve commendation. The survey was not designed to glorify the medical schools, and it has not done so.

Some may be disappointed that the survey does not blueprint a new philosophy or new program of medical education. Although such an approach might have been an interesting and stimulating one, the survey felt that its most useful approach would be to provide a glass into which each school could peer and ask itself which of the faults and failings of American medical education there mirrored are cast by its image. To a large degree the report of the survey has been successful in achieving this end, and the self-examination it is certain to stimulate in each school should lead to a very definite improvement in medical education in this country in the years immediately ahead.

As previously reported, a separate subcommittee was appointed by the survey to make a special study of preprofessional education as it relates to medicine. The report of this study which was supported by a grant from the John and Mary Markle Foundation, is now in press, and its publication later this fall is being eagerly awaited.[3]

First World Conference on Medical Education

This report is being written on the eve of the First World Conference on Medical Education to be held in London, Aug. 22-29, 1953, under the auspices of the World Medical Association. The holding of this conference bespeaks the growing recognition that medical education is of basic importance in all efforts to improve medical care and to advance medical knowledge. It also reflects the increasing extent to which thinking in medical education, as in medical science, is transcending national boundaries, with men from all parts of the world seeking to share experiences and knowledge with their colleagues in other countries.

Four fundamental subjects have been selected for discussion by representatives of medical schools from more than 40 countries. These subjects are (1) requirements for entry into medical schools; (2) aims and content of the medical curriculum; (3) techniques and methods of medical education, and (4) preventive and social medicine.

It is expected that the numerous representatives from the United States will not only contribute actively to the program of the Conference but will also benefit from the exchange of information, views, and philosophies concerning medical education as it is conducted in many other parts of the world. Arrangements have been made to have the proceedings of the conference published by the Oxford University Press.

Major Developments in the Medical Schools

Information of general interest concerning any major new developments during 1952-1953 was requested from the schools again this year. These data are reported under the headings of curricular changes, organization and administration, hospital affiliations, construction, and miscellaneous.

Revision, modification, or experimentation with the curriculum were reported by 16 schools. Medical educators will be especially interested in the radically new approach to undergraduate medical education that has been developed at Western Reserve University. Planning for this new program was begun in 1945 and the experiment has been subsidized by a grant totaling $728,000 given by the Commonwealth Fund. The objective is to provide a basic education that will prepare the student to become a family physician, specialist, teacher, or investigator. The unique features of the program are the methods by which correlated instruction is to be given in the biology of man, the principles of medicine, and care of the patient. Teaching is carried out by interdepartmental teaching committees in three phases, under the direction of a coordinator for each phase. The traditional departmental organization of teaching has therefore been abandoned and this policy is carried through to the laboratory phases of instruction. Instead of the usual departmental laboratories, each student is provided with his own laboratory where, throughout the year, he carries out all of his laboratory work.

Students are regarded as maturing individuals and as graduate students who are to be given increasing responsibility for their own education and free time in each year for the pursuit of elective studies.

The first class was enrolled in this program last fall, and this class will be graduated in 1956. While the first phase has been organized and activated, the second and third phases are not yet completely planned.

Phase 1, the first year, involves study of the normal biology of man, with a multi-disciplined approach to the study of organs and organ function rather than the usual study by separate disciplines. The biochemical activities of the body are stressed. In this phase students are also introduced to the normal infant, adult and family, and to the behavior of man as a member of society.

Phase 2, the second and third years, will emphasize the principles of medicine, prevention of disease, mechanisms of disease, and the natural history of disease. The approach will be from the standpoint of diseases of organs and systems instead of by the older division of teaching by separate special disciplines. A progressively increasing amount of clinical work will be introduced, with major emphasis on diagnosis and on the definition of the principles involved in the mechanisms of illness and of treatment.

Phase 3 will involve application of the material covered in the first two phases to the care of patients in the hospital and at home.

Space prohibits the presentation here of more than a bare outline of the background, the objectives, and the mechanics of this unique program. Those interested in a more detailed report are referred to a panel discussion by members of the medical faculty at Western Reserve, which is reported in the Proceedings of the Annual Congress on Medical Education and Licensure for 1953.

Other schools that reported curriculum changes or plans for such changes were Arkansas, Southern California, Indiana, Kansas, Louisville, Maryland, Harvard, Albany, New York Medical College, Cornell, Pennsylvania, Jefferson, Temple, South Carolina, and Southwestern. The general trends which have characterized postwar curriculum changes continued. Several schools reported programs designed to achieve integration of teaching of basic science subjects without regard for the traditional departmental lines. There were further reductions in the hours devoted to didactic teaching in the clinical years and substitution of increases in clinical clerkship assignments and in the time given to correlated clinical teaching. Several schools announced programs emphasizing comprehensive study of the patient through the development of general medical clinics, reduction in assignments to special clinics, and various types of family and home care plans. The new experimental course in comprehensive medicine at Cornell University is now in effect for all four classes.

---

[3] Severinghaus, A. E.; Carman, H. J., and Cadbury, W. E., Jr.: Preparation for Medical Education in the Liberal Arts College, New York, McGraw-Hill Book Co., to be published.

Administrative or organizational changes were reported by several schools. Louisville established new research laboratories for the department of biochemistry, a research laboratory for the department of surgery, and a department of physical medicine and rehabilitation. At Syracuse, full-time departments of preventive medicine and psychiatry have been organized and partially staffed, and a full-time professor and head for the department of pediatrics has been appointed. Albany has also appointed a full-time head for pediatrics. At Oregon the medical faculty has assumed responsibility for operation of the state crippled children's program. Temple University reported appointment of additional full-time teachers in clinical departments and the establishment of a new research laboratory for the department of physiology. The University of Washington has developed a hospital extension service in connection with the chronic disease unit at King County Hospital and the senior clerkship program. This is an experimental program designed to test the effectiveness, for certain selected, chronically ill patients, of home care as compared with hospital care. This school has also inaugurated surgical and obstetrical clerkships utilizing private patients in several affiliated hospitals.

Important changes in their hospital relationships were reported by several schools. Boston University has a new affiliation with the Boston City Hospital that permits the medical school to appoint a director of pediatric teaching for the hospital and permits the dean, professor of pediatrics, and director of pediatric teaching to nominate all appointments to the pediatric staff. This school has developed an affiliation, under a dean's committee, for graduate training in surgery and medicine, at the Providence Veterans Administration Hospital. The affiliation for obstetrical teaching in the Malden Hospital has been discontinued. The gynecological and obstetrical service at the Boston City Hospital has been reorganized and a new affiliation developed that will allow the deans of the three Boston medical schools to nominate the person to be appointed to the newly created full-time position of director of the gynecological and obstetric service. This makes possible the development of a cooperative teaching program in which all three schools will participate. Indiana this year assumed additional teaching and service obligations at the LaRue D. Carter Psychiatric Hospital, located on the medical center campus, and has also assumed responsibility in connection with the Cold Spring Road Veterans Administration Hospital for Tuberculosis. The University of Louisville has assumed professional responsibility for a geriatric hospital recently established by the city. North Carolina opened its new teaching hospital last year, and Mississippi began construction of a university hospital in December. Albany has consummated a new agreement with the Albany General Hospital under the terms of which the hospital has agreed to underwrite the major share of the clinical budget of the medical college.

Capital expenditures of the medical schools have been reported for the past three years. Beginning with 1951-1952, the schools were asked to report separately the amounts spent for projects completed and amounts spent for projects initiated. In this report, as in last year's, an effort has been made to exclude figures and projects that were reported in previous years.

Projects costing a total of $8,206,082 were completed during the past year. New clinical facilities or additional clinical facilities were completed at Kansas, Michigan, and Wisconsin. Additional laboratory space was constructed or old quarters were remodeled at Western Reserve and Tennessee. Student dormitories and an alumni building were constructed at Meharry.

For new projects initiated during the past year, the schools spent a total of $34,394,005. New medical school buildings or additions to existing buildings were reported by Indiana, Louisiana State, Harvard, Missouri, Minnesota, Brooklyn, New York University, North Carolina, Western Reserve, Oregon, Tennessee, and Southwestern. New clinical facilities or the expansion or renovation of existing facilities were started at Alabama, George Washington, Missouri, Washington University, Nebraska, Rochester, and Oregon. Yale and Cornell began the construction of student residences, and Kansas began a continuation center and student union.

The total of $42,600,087 spent for projects initiated or completed during 1952-1953 brings the gross total of such expenditures, during the past four years, to more than $284,000,000. Totals of $81,640,735 were reported for 1951-1952, $60,000,000 for 1950-1951, and more than $100,000,000 for 1949-1950. The sharp decrease in expenditures during the past year follows the completion, by many schools, of extensive programs of rehabilitation and expansion. Although such expenditures in the years immediately ahead can scarcely be expected to match the unprecedented expenditures of the years immediately following the end of World War II, the data for capital programs initiated last year indicate that substantial new construction will continue for several years at least.

However, it is important to keep in mind that a high proportion of the expenditures that have been reported have been for hospitals and dispensaries that, in addition to their essential role in medical education, have another important role to play in providing medical service to the public. A considerable share of these expenditures could therefore legitimately be charged to medical service rather than to medical education. Furthermore, the fact that many schools have been fortunate enough in recent years to acquire splendid new facilities should not obscure the fact that the needs of many schools have been only partially met. There remain a number of schools that are struggling under the handicap of seriously inadequate facilities for basic science teaching and shortages of facilities for research in the basic and the clinical sciences.

Several additional developments were important. Stanford University has received gifts, for the medical school, totaling $1,218,000 and North Carolina has received a grant of $160,000 from the Commonwealth Fund for support of a general outpatient clinic for two and a half years. The facilities of the Medical Center of the Medical College of Alabama have been surveyed by the Infantile Paralysis Foundation, Inc., and the foundation will supply funds for the hospitalization of certain patients with poliomyelitis.

Financial Support of Medical Schools

For the seventh successive year the medical schools report a major increase in the funds available to them for their operations. For the academic year 1953-1954, the budgets of the medical and basic science schools in the United States total approximately $87,409,000. This sum represents an increase of $6,524,000 in the past year and an increase of $13,059,000 in the past two years. During the seven year period that these figures have been compiled, the budgets of the medical schools have been increased by more than $39,524,000.

The total of $87,409,000 does not include research grants and special teaching grants from outside agencies or any significant portion of the cost of operating the teaching hospitals owned by or affiliated with the medical schools. It does include a total of approximately $3,475,000 that the medical schools will spend for certain activities in their teaching hospitals. This sum, which is approximately the same as in the previous year, is largely made up of salaries of professional and technical personnel on hospital staffs, the cost of operating special laboratories, and in a few instances contributions to the operating budgets of hospitals and dispensaries used by the medical schools for teaching purposes.

As in previous years, no attempt has been made to compute the direct and frequently very substantial contributions that a number of teaching hospitals make to the educational programs of their affiliated medical schools or to estimate the value of the services contributed by the large number of unpaid members of the teaching staffs of the medical schools. Where a charge for general university administration has been made against a medical school, this charge has been subtracted. Also not included are the cost of operating the medical library and the cost of plant maintenance in two schools and a variety of items, which total slightly more than $1,400,000, for minor structural alterations, postgraduate education, special institutes, and other activities not included in the regular medical school budgets. The costs of new major construction has also been eliminated from the above total. As already noted in the section on major developments in the medical schools, the schools during the past year were engaged in constructing new facilities of various types costing about $42,600,087.

The schools estimate that receipts from tuition and other fees during the coming year will total $18,041,000, or 20.6%, of their budget. Last year tuition fees provided $17,400,000 or 21.5% of the schools' budgets. The number of schools unable to match student fees dollar for dollar with funds from nonstudent sources in their basic budgets increased from six to seven. In at least two of these schools the situation is not so unfavorable as the figures would suggest, since in each instance hospital funds that do not appear in the medical school budget provide support for comparatively large full time clinical faculties.

The median budget of the four year medical schools for the coming year will be $1,040,000. Thirty-seven schools as compared to 33 last year and 30 the year before report budgets of over a million dollars for the coming year. Eleven of these schools will have budgets of over 2 million dollars. Last year six schools were in this category. Only six of the four year schools as compared with 11 last year report budgets of less than $500,000. Of these, two have budgets of less than $400,000.

In addition to the funds discussed in the foregoing paragraphs, the schools have estimated that during the academic year 1953-1954 they will receive from outside agencies a total of $38,200,000 in grants for research and $5,300,000 in grants for special teaching activities. Funds received in these categories last year totaled $40,100,000 and $5,534,000. Past experience has shown that the total amount received in grants usually exceeds substantially the amount that the schools estimate in advance, so that the foregoing figures should not be interpreted as indicating that the schools face a reduction in the amount of money they will receive in the form of research and teaching grants during the coming academic year.

In 1952-1953 all schools received funds in both of these categories. Among the four year schools the range in grants for research varied from $13,000 to $4,150,000. Twelve schools received more than one million dollars in grants for research and 14 other schools received between $500,000 and a million dollars. Last year the schools in these categories numbered 12 and 10 respectively.

TABLE 1.—*Recapitulation of Estimated Funds Available to Medical Schools, 1953-1954*

Funds for Construction and Operation of Major Clinical Facilities Not Included

Budgeted funds and appropriations	$ 87,409,000
Funds for miscellaneous projects	1,400,000
Research grants from outside agencies	38,200,000
Teaching grants from outside agencies	5,300,000
	$132,309,000

Table 1 recapitulates the funds that the medical schools will expend during the coming academic year in support of their activities exclusive of new construction and the operation of major clinical facilities. As emphasized in previous reports, it is important that it be understood that the total of $132,309,000 shown in the table will support many activities in addition to the instruction of undergraduate medical students. As is clearly demonstrated in the report of the Survey of Medical Education, a modern medical school conducts a broad program of instruction, research, and service. Tables 12 and 14 indicate the extent to which the medical schools are providing directly for the educational needs of large numbers of other students in addition to undergraduate medical students. Almost one-third of the total sum that will be expended by the medical schools next year is definitely earmarked for research and a smaller portion for the support of clinical services. Additional direct and indirect support of research and clinical services will undoubtedly be provided by the basic budgets of many medical schools, although the actual amount cannot be estimated.

Despite the steady increase in funds that have been made available to the medical schools in the past seven years, medical educators, pointing to the continuing inflation and the continuing demands that are being placed on the medical schools for more research, more service, and the expansion of their student bodies, have indicated that many schools are still operating under serious financial pressures. Faculty salaries by and large have not kept pace with the rising cost of living, and many schools have expressed real concern over their ability to hold their present faculties and even more concern over their ability to recruit able young teachers.

It is difficult at this time to estimate accurately the total current needs of the medical schools for additional operating funds. An intensive study of this problem has just been initiated by the Council on Medical Education and Hospitals and the Association of American Medical Colleges. The results of this study should be available late this year or early in 1954.

The last comprehensive study of this problem was made by the Surgeon General's Committee on Medical School Grants and Finances, which reported that, on the basis of figures compiled for the year 1947-1948, the schools needed an additional 40 million dollars. Since that time the sum of the funds available to the medical schools annually has increased by approximately $51,500,000. However, when consideration is given to the increase in costs and the expansion of the schools' activities in the interval, it is clear that this increase is not all net gain. Seven schools continue to operate on total budgets of less than $500,000. The persistent difficulty several of these schools are encountering in their efforts to secure more adequate support raises a question as to whether the universities or groups sponsoring these particular schools are in a position to continue to assume the responsibilities involved in the conduct of a modern medical school.

The National Fund for Medical Education and the American Medical Education Foundation

The last two Educational Numbers have included brief reports of the activities of the National Fund for Medical Education and the American Medical Education Foundation, two closely associated organizations engaged in raising unrestricted funds annually on a national basis to assist the medical schools in securing more adequate financial support.

In July, 1953, these organizations in their fourth series of grants distributed a total of $1,944,151.64 to the schools for use during the coming academic year. This latest sum increases to over $4,750,000 the total assistance provided the medical schools by these two organizations since the first grants were made in July, 1951. Both organizations are intensifying their activities, with the strong hope that through their combined efforts they will shortly be able to provide the medical schools with at least 10 million dollars annually to aid in meeting the operational costs of their educational programs.

Medical Education and National Defense

Since the onset of war in Korea, the Joint Committee on Medical Education in Time of National Emergency, representing the Council on Medical Education and Hospitals and the Association of American Medical Colleges, has collaborated closely with the Department of Defense, the Armed Forces, the Selective Service System, the Public Health Service, the Civil Defense Administration, and other governmental agencies in dealing with problems created for medical education by the defense needs of the country. This coordination of effort has been of material assistance in the development of programs and policies designed to cope with these problems. As a result, the needs of the armed forces for medical personnel have been met and at the same time the medical schools have been able to fulfill their other obligations to the nation by supplying an increasing flow of well-trained physicians.

The joint committee early recognized the need for long range plans to meet the medical requirements of the military and of civil defense and suggested that the medical curriculum be revised to give proper emphasis to subjects of importance to military medicine and other fields vital to national defense. The joint committee therefore appointed in November, 1950, a subcommittee on curriculum under the chairmanship of Dr. Stanley W. Olson to recommend appropriate changes in the medical curriculum. This committee, in consultation with representatives of the armed forces and the Public Health Service prepared and submitted to the joint committee an outline of the subject material of importance to military medicine and civil defense.[4] They recommended that this material be covered in already established courses rather than by new courses inserted in already crowded curriculums.

During the past year the Subcommittee on Medical Education for National Defense, in collaboration with representatives of the Department of Defense, the Public Health Service, and the Civil Defense Administration, has developed experimental programs designed to emphasize the aspects of medicine necessary to national defense and to interpret in constructive fashion, for the undergraduate medical student, his responsibilities for military service and his role in civil defense. Five medical schools were selected for the initial experiment: Buffalo, Cornell, Illinois, Vanderbilt, and California. Financing for the programs was provided by a grant of $75,000 obtained through the armed forces and the Armed Forces Medical Policy Council. Each of the institutions involved in the experiment appointed a coordinator who was instructed to use his own judgment in selecting what seemed to be the best means of implementing the new program in his own school.

In the past, instruction in military medicine was given at the undergraduate level largely through R. O. T. C. and reserve officer courses, which unduly emphasized military organization and administration. The present programs are based on the premise that instruction in military organization is better learned in the military setting; the medical school can make its best contribution to defense by thoroughly indoctrinating the student in fundamental principles of medicine, with appropriate emphasis on the application of those principles to military and civil disaster situations. In this way, education for defense should not interfere with the basic education of undergraduate students and can actually serve to enhance it.

The governmental agencies have made invaluable contributions to the success of these programs not only by financial support and by the participation of their representatives in planning conferences but also by sponsoring special conferences for faculty members and by supplying information, films, and other teaching materials.

---

[4] Suggestions for Supplementing the Medical Curriculum in Time of National Emergency, Report of the Joint Committee on Medical Education in Time of National Emergency, February, 1951.

The methods used by the five schools varied considerably. At California, Illinois, and Vanderbilt, the major emphasis was on instruction given to the first year class; at Buffalo and Cornell programs were instituted simultaneously for all four classes. At California the material was given as a separate course, Cornell and Vanderbilt incorporated the subject matter into existing courses, while Buffalo and Illinois combined the two approaches. Each school has prepared and submitted to the subcommittee a report of its first year's experience.

Reception of the new programs by both students and faculty has been excellent. Faculty interest has been significantly stimulated as a result of participation of faculty members in a series of special conferences, sponsored by the National Research Council, the Armed Forces Institute of Pathology and the Army Medical Service Graduate School, on problems of special importance in military medicine. The subjects for the six conferences were shock, forensic pathology, stress, biological warfare, leptospiral diseases, and problems of blood transfusion in the severely wounded. These conferences served to emphasize that information drawn from military medicine is valuable to those engaged in dealing with the problems of civilian defense and civilian disaster.

Since the experiments of this first year have been considered by the subcommittee, and by the government representatives concerned, to be signally successful, and because of the continuing demands of national defense programs, the subcommittee has recommended that, as rapidly as possible, opportunity to participate in the program be offered, on a voluntary basis, to other schools. The experience of the past year indicates that each participating school will need a grant of about $15,000 for the employment of a coordinator and to defray other expenses incurred in the program. At this date, it is not yet known whether such grants will be made available by the Department of Defense to other schools wishing to participate in the program.

SELECTIVE SERVICE SYSTEM

Responsibility for the primary classification of registrants rests with the Selective Service local boards. If a person or his employer (college, medical school, or hospital) has requested his deferment and he has been classified as available for military service, then the person or his employer may, within 10 days of the mailing of the classification notice, file an appeal. Should the state appeal board sustain the classification, the registrant or his employer may, if there is a dissenting vote in the appeal board, file a written request with the local board to have the decision appealed to the National Selective Service Appeal Board. If there is no dissenting vote, the state or national director of selective service may appeal the case to the President.

The College Student Certificate (SSS Form 109) has been prescribed for the use of institutions of higher learning including those of medicine, in furnishing to the local boards information regarding registrants who are enrolled as students in those institutions. These forms should be submitted to the local boards by the educational institution on request of the registrant. However, the mere filing of such a form does not constitute a request for occupational deferment since, in order to establish the right of appeal as an interested party, a written request from the college or employer for occupational deferment must accompany the form. The registrant has the right of appeal if exercised in the prescribed 10 days. He can make his appeal informally in writing.

Eligibility for Consideration for Deferment.—The law states that the President may provide for the deferment of any person whose deferment is equitable and in the national interest. He is also informed that it is the sense of the Congress that provision should be made for the annual deferment from training and service of premedical, predental, and allied preprofessional students in numbers equal to those at present in attendance at colleges and universities. This is being provided in the general student deferment program. The President is also directed to establish a National Advisory Committee to advise the Selective Service System and aid state and local advisory boards in selecting the needed medical, dental, and allied personnel.

The conditions under which students pursuing programs of higher education may be considered for deferment are specified in sections 1622.15 and 1622.25 of the Selective Service regulations. Within the specified requirements, students of the healing arts are to be considered for deferment in the same manner as students pursuing other undergraduate or graduate courses at colleges, universities, etc.

Any student not previously deferred who is pursuing a full time course of study is entitled to a single period of statutory deferment (Class I-S) until the end of the academic year. Such deferment does not preclude the possibility of his later deferment in Class II-S. Students whose activity in study, research, medical, or other endeavors is found necessary to maintenance of the national health, safety, or interest may be deferred in Class II-S until completion of their training, provided they maintain satisfactory scholastic records. A student who is deferred for study extends his liability for military training and service up to his 35th birthday instead of his 26th, as prescribed for registrants who have never enjoyed a deferment.

In selecting a student for deferment in Class II-S the Selective Service local boards may, at their discretion, be guided either by the score made by the student on the Selective Service College Qualification Test or by his record of academic performance.

The College Qualification Test is given for the Selective Service System by the Educational Testing Service of Princeton, New Jersey. At present, in order to be eligible for deferment on the basis of this test, an undergraduate student must make a score of 70 or more. SSS Form 108 has been prescribed for furnishing to the local board the score made on the test. This score is confidential and may be divulged by the local board only to the registrant or one holding his written consent.

To qualify for deferment on the basis of academic performance, the nonprofessional student must have maintained the following standing among the male members of his class: freshman year, upper one-half;

sophomore year, upper two-thirds; junior year, upper three-fourths.

By Selective Service Regulations a student accepted in medical school on or before July 1, 1951, and who is satisfactorily pursuing full time courses of study may be deferred without consideration of class standing or the Selective Service qualification test if the college certifies him as a full time student satisfactorily pursuing his courses.

A student accepted for admission to medical school after July 1, 1951, for the class next commencing may be deferred provided that during his last full time year at a college or university he was ranked among the upper one-half of the male members of his class or had a score of 70 or more on the Selective Service College Qualification Test. A student admitted to a graduate school before July 1, 1951, who is pursuing a full time course of study may be deferred provided he is meeting degree requirements. A student accepted for admission by a graduate school after July 1, 1951, as a full time student for the class next commencing may be deferred provided in his last full time academic year in a college or university he achieves a scholastic standing among the upper one-half of the male members of his class or scored 75 or more on the qualification test, and provided the graduate school certifies that he is meeting the degree requirements.

Decisions concerning deferment of American students enrolled in foreign universities, including medical students, are the responsibility of the local boards. The local board may accept or reject any claims or evidence presented for deferment.

Interns and Residents.—The Selective Service System has always recommended the deferment of graduates of medicine to complete one year of internship training. No statement of policy has been issued by the national headquarters of the Selective Service System with respect to residents or second year interns.

The National Advisory Committee to the Selective Service System has indicated that all physicians in priorities 1 and 2 will be needed by the armed forces and has advised that they apply for commissions about the time of completion of their internships. A few persons in these categories may be recommended for deferment by the Selective Service Local Boards for teaching, research, or public health service or because they are rendering essential service in isolated communities and cannot be replaced.

In addition, the only persons in this group who can justifiably be recommended for deferment are those who are accepted for training in the scarcity specialties and whose services are required to meet essential needs of medical and dental schools or hospital services. The specialties in which critical shortages exist are anesthesiology, physical medicine and rehabilitation, psychiatry, radiology, neurology, pathology, public health, orthopedic surgery, oral surgery, and the basic medical sciences. Those few persons in these groups for whom deferment is necessary may be deferred in class 2-A by the Selective Service local board. The recommendation of the advisory groups in all such cases is desirable.

Faculty Members.—A majority of the faculty members of medical schools are under age 50 and, therefore, are required to register with the Selective Service System as required under Public Law 779. No policy has been announced by Selective Service on the granting of deferment to faculty members. However, the National Advisory Committee has recommended that, as a general policy, essential members of medical, dental, and veterinary medical faculties be held in their teaching positions rather than be released for military service. This recommendation applies especially to men in the basic science departments and includes persons in priorities 1 and 2. This policy is not a blanket recommendation for deferment from military service for all teachers. Part time teachers who devote only a small part of their time to teaching, and certain of the younger full time teachers in priorities 1 and 2 will be expected to enter the military services.

THE DOCTOR DRAFT LAW OF 1953

Public Law 84, 83rd Congress, approved by the President June 29, 1953, amended the Universal Military Training and Service Act. It, and the previous amendment, Public Law 779, 81st Congress, are known as "The Doctor Draft Law."

The effective date of the whole Universal Military Training and Service Act, as now amended, is extended to July 1, 1955. No change was made in the age limit prescribed in the previous amendments which required that all physicians, dentists and allied specialists, under the age of 50, must register with their Selective Service local boards, when required to do so by proclamation of the President. These special registrants remain liable for induction up to the age of 51. Therefore, all new medical graduates under the age of 50 must register with their Selective Service local boards as physicians, regardless of any previous registration, within five days of the receipt of the degree of Doctor of Medicine. When the degree is not granted until the completion of an internship, this special registration is accordingly deferred.

As under previous provisions of the act, registrants will be arranged in four priorities signifying the order of induction. However, the criteria for such an arrangement under these priorities have been modified. The major changes enacted by the new amendment are those which provide for greater recognition of prior military service. A registrant will now receive credit for all service performed either as an officer, or as an enlisted man, since Sept. 16, 1940, regardless of whether it was before or after participation in an AST or V-12 program, or deferment by the Selective Service System for professional education prior to March 31, 1947. Also recognition is given for military service performed in the armed forces of a country allied with the United States prior to Sept. 2, 1945, while so allied.

Whereas formerly physicians who were educated in part, or in whole, at government expense, or were deferred by the Selective Service System while completing their professional education, needed 21 months of service to qualify for arrangement in priority 4, they now need only 17 months. As the result of this change, a number of physicians formerly in priorities 1 and 2 will be rearranged in priority 4. The periods of service for men called to active duty or inducted under the new law were

* Ninety semester hours for veterans.

** Intern enrolment not included in total column.

† Figures represent two classes. Intern year requirement discontinued.

also revised. Those with 9 months or less of service must serve 24 months. Those with 9 to 12 months will serve 21 months. Those with 12 to 15 months service will serve 18 months, and those with 15 to 21 months service will serve 15 months. Those physicians in priority 4 who have had 21 months or more of service since Sept. 16, 1940, are no longer liable for induction or recall to duty, except in time of war or national emergency declared by Congress.

* Expanded to four year medical school. Enrollment for third year class in 1952-1953 was 48.

"Active service" and "active duty" are defined as: full time duty since Sept. 16, 1940 in the service of the United States Army, Navy, Marine Corps, Coast Guard, or Public Health Service, including reserve components; time spent during World War II, by conscientious objectors, in work of national importance; service performed before Sept. 2, 1945 in armed forces of countries which were allies of the United States during World War II; service performed as a physician or dentist employed by the Panama Canal Health Department between Sept. 16, 1940, and Sept. 2, 1945.

Specifically excluded from consideration as "active service" is time spent in V-12 or AST programs, in military internships, residencies or senior student programs, time spent in military service for the sole purpose of undergoing physical examination, and training entered into after June 29, 1953.

The law continues to permit the deferment of those persons whose activities are essential to the national health, safety, or interest.

It is the duty of the National Advisory Committee and the voluntary state and local committees of the Selective Service System to make recommendations to the Selective Service System concerning the essentiality or availability of special registrants who are being classified by their local boards. This duty includes recommendations concerning residents, faculty members, and those engaged in essential laboratory and clinical research.

Korean "G. I. Bill"

A detailed analysis of the Korean "G. I. Bill" (Public Law 550, 2nd Session, 82nd Congress) was presented in last year's Educational Number. It may be expected that an increasing number of veterans will utilize the benefits provided by this law to obtain their premedical or medical education. Likewise, many physician veterans on their release from service will undoubtedly take additional graduate education under the provisions of the law. The Veterans Administration has ruled that both internships and residencies will be classified as institutional type training for the purpose of this law. This ruling corrects the unsatisfactory situation existing under the original "G. I. Bill," whereby internships and general practice residencies were treated as on-the-job training and residencies in the specialties were classified as institutional programs.

Approved Medical Schools

The 72 medical schools in the United States that are approved by the Council on Medical Education and Hospitals are listed in table 2; the 10 approved Canadian schools are named in table 3. The 8 approved schools of the basic medical sciences in the United States and Canada are listed in table 4. There has been no change in the lists since the publication of the 1952 Educational Number.

These tables give the number of years of premedical training that each school will require of freshmen entering in 1954. They also list the number of students enrolled in each class for the academic year 1952-1953, the number of students enrolled in internships that are a part of the degree requirement, and the number of students graduated by each school from July 1, 1952, to June 30, 1953. For the Canadian schools enrollments are given for premedical students, students enrolled in a fifth medical year, and those in a required intern year.

The name of the dean or executive officer appears opposite the name of each school. Changes in the chief executive officers have been made by 17 of the 90 medical and basic science schools of the United States and Canada since publication of the 1952 Educational Number. New executive officers have been appointed by Stanford, Georgetown, Georgia, Illinois, Iowa, Johns Hopkins, Tufts, St. Louis, Albany, Cornell, Rochester, Baylor, Virginia, Washington, Missouri, North Dakota, and Southern California.

Medical School Calendars

Conventional schedules were followed during the 1952-1953 academic year by most schools, with students entering in September or October and graduating in May or June. Schedules for the freshman class will be the same in all schools for 1953 as for 1952.

At Kansas, where the freshman year consists of two semesters and a summer session, with vacations and periods of instruction staggered, half the freshmen began their studies in June and half in September. Graduation is in June. The University of Tennessee admitted students each quarter and graduated a class each quarter.

At Duke University, the academic year consists of three quarters each year. There is no summer quarter between the first and second year, but in the two clinical years the subjects of the autumn, winter, and spring terms are repeated in the summer quarter. This accelerated schedule is optional, and students may take their first year and three quarters in each of their subsequent years and receive their certificates in four calendar years; if they receive permission from the curriculum committee, they may at the end of their second year take the clinical quarters given during the summer and receive their certificates in three and one-quarter calendar years. Freshmen are admitted in September only.

Freshmen students are admitted to the University of Chicago annually in September. They may, however, elect to accelerate their programs and graduate in a minimum of approximately three and one-quarter years.

The University of Utah, which had been on an accelerated program, returned to a conventional schedule for the class entering in September, 1951. During the transition the upper classes will complete their medical course on an accelerated schedule. Mississippi continued to admit a class in July and one in January. Canadian medical schools followed regular schedules during the past year and will continue to do so in the coming year.

Scheduled Clock Hours of Instruction

The schools were requested to estimate the approximate total of hours scheduled for each class enrolled during the 1953-1954 academic year. The 73 schools reporting on the first two years had an average of 1,152 hours scheduled for the first year and 1,156 hours for the second year. For the first year, the lowest number of scheduled hours reported was 804 and the highest was 1,521; for the second year the low was 864 hours and the high was 1,548 hours. Sixty-six schools reported an average of 1,318 hours in the third year, with a low of 751 and a high of 2,119. Sixty-five schools that gave figures for the fourth year had an average of 1,421 hours, with a low of 944 and a high of 2,376.

Comments that accompanied many of these estimates of scheduled hours make it clear that the figures from different schools, as furnished, are not comparable and do not always reflect accurately the total hours of instruction that are given. Some schools did not include as regularly scheduled hours time devoted to elective courses and other schools excluded night duty that constitutes a regular part of clinical clerkship assignments. An additional variable is introduced by the difference in the length of the academic year, which may range from two semesters to four quarters in length.

Enrollments

For the fifth consecutive year the total number of students enrolled in approved medical schools in the United States established a new record. Enrollment in the 72 medical and 7 basic science schools during 1952-1953 totalled 27,688 as compared to 27,076 in the previous year. There was an increase in total enrollment of 612, or 2.3%. There was, however, for the first time in five years, a slight decrease in the size of the entering freshman class. This class, numbering 7,425, was smaller by 16, or 0.2% than last year's entering class. This leveling off in the size of the freshman class, following four consecutive entering classes of record size, is expected to be temporary. New facilities now in operation and expansion programs soon to be completed should provide further significant expansion of enrollments.

When students now enrolled in the medical schools of the University of California at Los Angeles, the University of Miami, the University of North Carolina and the University of Puerto Rico are included, the total enrollment is increased by 279. However, these schools are not in full operation and consequently not yet eligible for Council approval. Their enrollment figures, therefore, may not be added to the present official totals.

TABLE 5.—*Enrollments by Classes in Medical Schools of the United States and Canada, 1952-1953*

---

* Does not include 472 premedical and 57 fifth year students.
† Does not include 395 premedical and 194 fifth year students.

Enrollment figures for each approved school are given in tables 2 and 4 and total enrollments for all approved medical schools and basic science schools in the United States and Canada are summarized in table 5.

In addition to students regularly enrolled as full time students of medicine, the schools had enrolled a total of 140 part time and special students working toward the M.D. degree.

Total enrollment in the 10 medical schools and one basic science school in Canada was 3,444, a decrease of 14, or 0.4%, since last year. These schools had 472 additional students enrolled in two premedical years and 57 in an additional (not intern) year. These additional students are included in the "total" column of table 3 and are not included in table 5.

There were 783 students in the United States and Canada who were enrolled in internships that were a part of the degree requirement of the medical schools at which they were educated. The total number of students enrolled in such internships in the United States for each academic year since 1930-1931 is shown in table 6.

Total enrollments, by classes, in the medical and basic science schools of the United States, for each academic year since 1930-1931 are shown in table 7. For years prior to 1942-1943, the totals given in table 7 are somewhat higher than the sum of the figures for the various classes in a given year. This discrepancy was due to the inability of certain schools, in those earlier years, to classify their students strictly into conventional classes.

* Includes additional classes.

In table 8, the medical schools of the United States are ranked according to the size of their student bodies. Enrollments ranged from 181 to 713 with a median of 447 and an average of 377.

In addition to regularly enrolled medical students, there were 140 part time or special students working toward the M.D. degree in medical schools in the United States and two such students in Canadian schools. The distribution of these students, by schools, is recorded in the first column of table 14.

TABLE 7.—*Students in the Medical and Basic Science Schools in the United States, 1931-1953*

* Includes additional classes.

Graduates

The 6,668 students graduated during the past year constitute the largest group ever graduated in one academic year from medical schools in the United States. This total exceeds by 279, or 4.4%, the previous record established in 1947, when at the termination of the wartime accelerated program several schools graduated more than one class. Tables 2 and 3 show, respectively, the number of students graduated from each approved medical school in the United States and Canada.

The total number of class A and approved medical schools, together with the total numbers of their students and graduates for each year since 1910 is shown in table 9. Similar figures for class B and C schools for the years 1910-1929 are recorded in table 10. The A, B, C classification of medical schools, inaugurated by the Council in 1910, was discontinued in 1929. Since 1929 schools have been classified as "approved," which is equivalent to the former class A, or as "unapproved." This fact should be borne in mind by those who desire to make comparative studies on the production of physicians at different periods.

TABLE 8.—*Medical Schools of the United States in Order of Size of Total Enrollment, 1952-1953*

Four Year Medical Schools	
University of [illegible]	713

University of Missouri	83
University of North Dakota	72
University of South Dakota	63
University of West Virginia	60
Dartmouth Medical School	48

The schools with the largest numbers of graduates during the past academic year were Illinois 174, Jefferson 160, Tennessee 155, Harvard 148 and the State University of New York College of Medicine at New York City 140. Four schools had less than 50 graduates, including Albany with 47, Woman's Medical College with 46, Vermont with 42, and Utah with 26. The University of Minnesota and the College of Medical Evangelists this year abolished a required intern year and, therefore, gave diplomas to two classes which numbered 232 and 191 respectively.

TABLE 9.—*Schools, Students*[1] *and Graduates in Approved Medical Schools,*[2] *(Class A) in the United States, 1910-1953*

1. Includes figures for schools of the basic medical sciences.

Increases in the size of graduating classes were reported by 46 schools for the 1952-1953 academic year, and decreases were reported by 18; 6 had the same number as the previous year.

The Canadian medical schools reported 825 graduates, 42 more than for 1951-1952. The largest numbers were graduated by Toronto with 162 and McGill with 115; the smallest classes were at Alberta and Queens with 52 each.

The estimated number of graduates for 1953-1954, based on enrollments reported for senior classes in schools in the United States, is 6,831; for the Canadian schools it is 867.

There was an increase in both the number and the percentage of medical graduates in the United States and Canada who had baccalaureate degrees. Table 11 shows that 5,725, or 85.8%, of all medical graduates in the United States and 494, or 59.5%, of Canadian graduates held baccalaureate degrees.

Responsibility of Medical Schools for Other Students

In recent years, increasing recognition has been given to the heavy burden of instruction that medical faculties must assume over and above their regular programs for undergraduate medical students. Medical faculties provide part or all of the instruction given to large numbers of students, other than medical students, at both the undergraduate and graduate levels. That an attempt should be made, in any study of the cost of medical education, to segregate the cost of these additional programs has been emphasized in previous issues of this report.

The extent of these extra duties is indicated by the figures reported in tables 12 and 13. In previous years, these figures were summarized in a single table. However, this year, in order to identify the groups of extra students more clearly, graduate students and physicians working toward advanced degrees have been listed in a separate table.

Table 12 shows by general categories the numbers of students for whom medical schools were responsible other than undergraduate medical students and graduate students who are candidates for advanced degrees. In the groups presented in this table were a total of 50,445 students. Medical faculties provided full courses of instruction for students in technical schools, interns, residents, and fellows in the medical specialties and in some instances dental students also. The total numbers of such students was 14,811.

Table 13 summarizes the gross total figures, collected since 1947-1948, concerning students other than medical students who have received instruction from medical schools. Since statistics for the years 1947-1948 through 1949-1950 are incomplete in some categories, the total figures for those years should not be compared with those for subsequent years. It should also be noted that the figures for graduate students have now been entirely deleted from table 12. The gross total of 50,445, from table 12, when combined with the total figures for graduate students recorded in table 14 gives a grand total of 54,149 other students who received instruction from medical faculties. This is less by 1,288 than the total reported the previous year.

There were significant increases in the number of technical students (646), nursing students (460), interns (322), and residents (335). On the other hand, there were major decreases in the numbers of physicians enrolled in refresher courses (1,428), nonmedical students taking medical courses (1,059), dental students (455), and pharmacy students (375).

The numbers of physicians and graduate students working toward advanced degrees in medical school departments are recorded in four groups in tables 14 and 15. There were 1,419 physicians working toward advanced degrees in medical school departments and 2,285 additional graduate students enrolled in programs leading to advanced degrees in the basic medical sciences. During

the past academic year, the Master of Science degree was awarded to 502 persons for completion of graduate work in Medical school departments and the Doctor of Philosophy degree to 258. While the number of graduate students in the basic medical sciences is only 25 less than last year, there was a decrease of 486 in the number of physicians working toward advanced degrees. As a consequence there has been a decrease of 511, or 12.1%, in the number of physicians and graduate students taking advanced work in medical school departments. In the basic medical sciences alone in the past two years the number of graduate students has shrunk by 15.7%. These figures are of the utmost importance, since a continuing decline in the ranks of potential teachers trained in the basic medical sciences will accentuate the already existing shortage of teaching and research personnel trained in these vitally important fields.

Canadian medical schools reported a gross total of 3,887 students other than medical students who received instruction from their medical schools last year. This represents a decrease of 601. The number of graduate students working toward advanced degrees in the basic medical sciences decreased from 160 to 129 while the number of physicians working toward advanced degrees increased from 106 to 256. The total number of students other than graduate students and undergraduate medical students for whom these schools were responsible was 3,502. A marked drop in the number of nursing students (980) more than offset increases in the numbers of nonmedical students taking medical courses (61), technical students (53), physicians enrolled in refresher courses (51), and pharmacy students (41).

Distribution of Students by Sex

Classification by sex of all students enrolled in medical and basic science schools in the United States and Canada for the academic year 1952-1953 is given in table 16. This table also records similar data for the graduates of each school.

The total number of women students and graduates and the proportion of women to all persons in these categories is given for each year since 1905 in table 18. Figures for the years 1905 through 1929 include statistics for class B and C schools; those for 1930 and subsequent years represent only approved schools.

There were 1,463 women in medical and basic science schools in the United States during 1952-1953, 8 less than last year. However, there were proportionately about the same number of women in medical school and entering medical school this year as in the previous year. They comprised 5.3% of all students as compared with 5.4% last year. Women in freshman classes totaled 399, or 5.3%, of the total as compared with 394, or 5.3%, last year. Women this year constituted 6.1% of all applicants to medical school as compared with 5.6% last year. The actual number of women graduates increased slightly. There were 363 women graduates, or 5.5% of the total, as compared with 351, or 5.7%, the previous year. Dartmouth and Jefferson had no women students and Woman's Medical College no men. The number of schools with more than 30 women was eight, one less than the previous year. Canadian schools had 224 women enrolled, or 6.5% of all students, and had 46 women graduates, constituting 5.5% of the total.

TABLE 18.—*Women in Medicine in the United States*

Year	Women Students	Percentage of All Students	Women Graduates	Percentage of All Graduates
1905	1,073	4.1	219	4.0

TABLE 19.—*Enrollment by Classes of Veterans and Non-Veterans in the Medical and Basic Science Schools in the United States, 1952-1953*

	Men Veterans	Other Men	Total Men	Women Veterans	Other Women	Total Women	Total Men and Women
Freshmen	1,115	5,911	7,026	4	395	399	7,425
Sophomores	1,473	5,236	6,709	7	347	354	7,063
Juniors	2,314	4,062	6,376	12	337	349	6,725
Seniors	3,004	3,110	6,114	13	348	361	6,475
Totals	7,906	18,319	26,225	36	1,427	1,463	27,688

Negro Medical Students

There were 715 Negro medical students, 2.6% of all students, enrolled in medical schools in the United States during 1952-1953. These students were enrolled in 49 schools, with 265 at Howard University, 259 at Meharry, and 191 at other schools. There were 203 freshmen, 180 sophomores, 168 juniors, and 164 seniors.

Veterans in Medical Schools

The number of veterans enrolled in medical and basic science schools declined again for the second year. There were 7,942 veterans enrolled, comprising 28.7% of the total student body, as compared with 11,436, or 42.2%, last year. There were 36 women veterans.

Enrollment figures for veteran and nonveteran students are recapitulated in table 19. The number of veterans enrolled continues to decline and the present freshman class has the smallest complement of veterans for any year since the end of World War II. Veterans comprised 15.2% of the freshman class or 7.3% less than last year. The percentages of veterans in other classes were: sophomores 21%, juniors, 34.6%, and seniors, 46.6%.

Stalnaker, John M. "The Study of Applicants for Admission to United States Medical Colleges, Class Entering in 1952-1953." Reprinted, with permission, from J. Med. Educ. 28:21-28, Feb. 1953.

Geographic Source of Freshman Students

The residence of students at the time of their enrollment in the 1952-1953 freshman class in each medical and basic science school in the United States and Canada is given in table 17. Since persons frequently change residence and may move to states other than those in which they were born, the home states listed in this table are not necessarily the states either of birth or of permanent residence.

The residences of 886 freshmen in Canadian schools are given at the bottom of table 17. This total differs from the total given in other tables, since it includes figures for the first classes of premedical students who are already registered at Queen's University, Laval, and Toronto.

There were 14 schools that excluded all out-of-state students, one less than last year. There were five schools that admitted less than five out-of-state students.

Of the total of 3,677 freshmen admitted last year to state and municipally owned schools in the United States, 335, or 9.1%, were nonresidents as compared with 283, or 7.7%, the previous year. The percentage of nonresident students enrolled in these schools remains substantially below the 17.1% enrolled in 1941-1942, the last prewar year. In the privately owned schools last year 2,001 students, or 53.4%, were residents of states other than that in which the school was located. This is approximately the same proportion of out-of-state students admitted by these schools the previous year.

"The Study of Applicants" [5] prepared by the Association of American Medical Colleges provides additional interesting data on the geographic origins of medical students in the 1952-1953 freshman class. Table 20, which is reproduced from Mr. Stalnaker's study, presents an analysis of the total numbers of male and female applicants from each state, territory, and so on, together with the numbers accepted and rejected. About half of all applicants came from seven states. Ranked in order of the numbers of their applicants, these states were New York, Pennsylvania, California, Ohio, Illinois, New Jersey, and Texas. The first three of these states, New York, Pennsylvania, and California, each had approximately the same proportion of applicants admitted to medical schools (37 to 39%).

The total number of resident students, students from other states, students from territories and possessions of the United States, Canadian students, and students from foreign countries enrolled in each school in the United States and Canada are recapitulated in table 21. The number of first year students per 100,000 of population for each state is given in table 22. For the entire nation, there were 4.7 freshman medical students per 100,000 of inhabitants, approximately the same number as last year. The 11 states that have no medical or basic science schools had an average of 3.7 first year students, the same number as last year. States that have medical schools had 4.9 students per 100,000 of population as compared with 5.2 last year and 4.9 the year before last.

[1] Population Estimates, Current Population Reports. July 1, 1952, Series P-25, No. 70, March 24, 1953, Washington, D. C.

Forty students from United States territories and possessions were admitted last year, 14 less than in 1951-1952. Ten Canadians, three more than last year, were admitted to medical schools in the United States. Of the 886 students entering Canadian schools, 75 or 23 more than last year were from the United States; 27 students entering those schools were from foreign countries.

[1] Degree not withheld until internship completed.

Required Internships

The four schools in the United States and the five schools in Canada that require their students to complete an internship are listed in table 23. The discontinuance of this requirement by the College of Medical Evangelists and University of Minnesota during the current year represents the only change in the list since 1952. Although only these few schools require an internship, more than 99% of all medical graduates have for many years voluntarily served internships. In addition, a high proportion of medical graduates take additional hospital training after the internship.

Duke University gives the M.D. degree at the end of the four year medical course, but requires its students to sign a written agreement that they will spend two years training in a hospital or laboratory before entering practice. Several other schools permit substitution of a year of laboratory work for the internship. The number of United States students enrolled in intern years required by their schools is shown in table 6.

One year of internship is required as a prerequisite to licensure by the licensing boards of 26 states, the District of Columbia, Puerto Rico, and 5 territories and possessions. The internship requirement was instituted during the past year by South Carolina. Eleven boards require a rotating internship.

A list of boards with specific requirements for internships appears in table 24. Licenses of candidates from schools that require an internship are withheld by 10 states until completion of the internship (California, Connecticut, Iowa, Michigan, Oklahoma, Tennessee, Utah, Vermont, Washington, and Wisconsin). Certain states in addition to those listed in table 24 require internships of foreign medical graduates and of candidates seeking licensure on the basis of reciprocity or endorsement.

* Some states require the internship for graduates of medical faculties abroad and from reciprocity or endorsement applicants.

[1] Straight internship required.

[2] Internship must be a rotating service.

[3] Twenty-four month mixed or straight internship acceptable.

[4] Two year residency in a specialty or one year of postgraduate work accepted.

[5] Active practice for four years accepted in lieu of internship.

Hospitals approved for intern training by the Council on Medical Education and Hospitals of the American Medical Association are generally acceptable in those states that require an internship for licensure. The current list of approved internships will be published in the Sept. 26, 1953, issue of THE JOURNAL.

Preprofessional Requirements

The minimum educational requirement of the Council on Medical Education and Hospitals for students entering medical school after January, 1953, is three years of college training. Prior to this year the Council since 1918 had required two years of college and since 1938 had recommended three years. Although the present minimum requirement is three years, it is recommended that, in order to acquire a broad general education, premedical students take the full four year college course. In rare instances a medical school will be justified in admitting an exceptionally qualified student at the end of two years of college.

All state licensing boards require that an applicant for licensure present evidence of having completed at least two years of premedical study in college. Six states and Puerto Rico require three years. In tables 2, 3, and 4, the number of years of premedical work required by each medical school are shown.

College Record of the 1952-1953 Freshman Class

For the past three years, data have been reported on the scholastic records of students entering medical school. Since the colleges and universities use a number of different grading scales, it has been difficult to obtain data that are comparable. In previous years, the medical schools were asked to report the numbers of "A," "B," and "C" students admitted. Since a majority of institutions now prefer one of the numerical systems of grading, the medical schools were asked this year to report their figures on a four point scale in which 4.0 represents the highest grade attainable. For purposes of comparison, it should be noted that a grade of 3.6 to 4.0 on this scale is approximately equivalent to an "A" on the previous one, 2.6 to 3.5 grade a "B," and 1.6 to 2.5 equals a "C." The schools were requested to report the premedical scholastic records of the 1952 freshman class in three categories: those with grade point averages of 3.6 to 4.0, those with averages of 2 6 to 3.5, and those with averages of 1.6 to 2.5.

Seventy of the 79 medical and basic science schools in the United States were able to provide the data requested. Of the 6,491 freshman for whom figures are available, 18 0% had averages of 3.6 to 4.0, 67.5% had averages of 2.6 to 3.5, and 14.5% had averages of 1.6 to 2.5. Sixty-nine schools admitted students with college averages of 3.6 to 4.0. In this group fell 1,165 students, or 18.0% of the total. The largest number of such students admitted to one school was 96. All schools admitted students with averages of 2.6 to 3.5 and 4,384, or 67.5%, were in this category. Fifty-eight schools admitted students with averages of 1.6 to 2.5 and 942 students or 14.5% of the total were in this bracket. The largest number of students from this group admitted by one school was 94.

While the figures may not be strictly comparable to those compiled in previous years, it is worthy of note that while the proportion of students in the lowest grade bracket is about the same as last year (15%), there has been a decrease of 12% in the number in the highest bracket and a proportional increase in the middle group. It is of particular interest to note that in the 1950 freshman class, 40% of the students had "A" averages while 9.1% had "C" averages. In other words, while the proportion of students in the lower grade category has increased by about 5% in the past three years, the proportion in the highest category (A or 3.6 to 4.0) has decreased by 22%.

Official figures on the number of applicants to medical schools in the United States have been compiled by the Association of American Medical Colleges [5] from data provided by the schools. The number of individuals who applied for admission in the year 1952-1953 was 16,763 as compared with 19,920 in 1951-1952. This represents a decrease of 3,157 and is 5,516 less than the number who applied in 1950-1951. This is the fourth consecutive year in which the number of individual applicants has decreased, and this year's group is smaller by 7,671, or 31.4%, than that of the peak postwar year 1949-1950. Since 7,425 students were admitted to medical school during the past academic year, it may be calculated that one out of each 2.26 applicants was accepted. Last year, the ratio was one out of 2.68 students and in 1949-1950 it was one for 3.47.

It is also reported in this study that 5,215, or 31.1%, of those applying for admission in the 1951-1952 class had applied and been rejected during the previous year. Of this group, 38.5% were accepted last year. Among those applying to medical school for the first time in 1952-1953, 47.3% were accepted.

This report has emphasized in recent years that the difficulty of gaining admission to medical school has been grossly exaggerated. The statistics presented here amply confirm this fact. The situation in the past year, when there were 2.6 applicants for each place in medical school, was approximately comparable to the year 1929-1930 when there were 2.1 applicants for each available place.

The decline in the ratio of applicants to available places in medical school that has occurred in the past three years has been due not only to a decrease in the actual number of applicants but also to the significant expansion in the facilities for training physicians that has taken place in recent years, an expansion that is still continuing.

There are probably a number of causes for the shrinkage in the size of the applicant pool, and a complete analysis of this problem cannot be undertaken here. However, one major factor is the disappearance of the large backlog of veterans who completed their premedical training following the termination of World War II. Another factor, one that is certain to cause serious concern among medical educators, is the sharp decrease in the number of applicants with superior academic records. While, again, one can only speculate as to the cause, it seems likely that this drop is in no small measure due to increasing competition for such talent from other professional fields. If the present trend continues, many medical schools in this country may soon find themselves hard pressed to recruit adequate compliments of well-qualified students.

The 1953 Freshman Class

The 1952-1953 freshman class, with 7,425 students, was slightly smaller than the record class of 7,441 admitted in 1951-1952. Figures at present available suggest that the 1953-1954 freshman class may show some further slight reduction in the number of students admitted. This leveling off after a period of rapid and marked expansion in enrollments perhaps reflects an adjustment to operation of the present schools at or near their maximum capacity. However, there will be further, significant increases in enrollments when certain established schools complete expansion programs that are now under way and when several new schools, now in the final stages of development, are completed.

By June of this year the schools had already selected 7,068 students. Among the 6,646 men, 851, or 12.8%, were veterans (242, or 12.8%, less than the previous year). There were 422 women, of whom 4 were veterans. The Canadian schools by June had enrolled 675 students; the expected enrollment is 928.

Preparation for General Practice

Medical faculties and medical students alike show a continuing interest in education for family or general practice. Many medical schools report that their primary objective is the preparation of students for general practice and that the major emphasis in their teaching is on education for work in this field. A high proportion of the schools sponsor one or more programs specifically designed to introduce students to this type of practice.

The general objective of preparing students for general practice is implemented in a variety of ways in different schools. At the undergraduate level, this is accomplished through general practice preceptorships, home care and family study programs, general practice clinics, substitution of clerkships in general medical clinics for specialty clinic assignments, and lectures by outstanding general practitioners on the nature of general practice and the opportunities that it offers. In a number of states, scholarship funds have been established for the support of students who wish to practice in small towns or rural areas. Some schools have arranged affiliations with rural hospitals where students are assigned for a part of their clinical clerkship training. In their affiliated hospitals, 25 schools have organized internships and 18 are sponsoring residencies particularly designed to equip the physician for general practice.

Preceptorship Programs

Experimentation with general practice preceptorships is being continued in a number of schools. Three schools that formerly had such programs will discontinue them this year and one school which had planned to initiate a program in 1953 still has the plan under consideration. Thus, the total number of schools having such programs will be reduced from 25 to 21. Table 25 lists the schools that have established preceptorships.

The preceptorship is a required part of the medical course in 10 schools, 1 more than last year, and was elective in 11. The duration of preceptorship assignments ranges from 2 to 12 weeks, with an average of approximately 6 weeks. All of these programs are scheduled either during the summer between the third and fourth years or during the fourth year except at one of the two year basic science schools. Nineteen schools reported that last year a total of 917 students served preceptorship assignments.

Table 25.—*Medical Schools Offering Preceptorship Programs, 1952-1953*

University of Wisconsin

The faculties of 18 schools were reported to be in general satisfied with the preceptorships. It may be assumed that the three schools that discontinued such programs had not found them satisfactory; two additional schools, although indicating some dissatisfaction, are continuing the program.

Student Fees

Resident tuition fees in the 72 medical schools and the 7 schools of the basic medical sciences in the United States for the academic year 1953-1954 will range from $99 to $968 except for one school, which will charge a fee of $1,291. The median fee will be $715 as compared with $689 last year. The average fee will be $633 as compared with $623 in 1952-1953. Only 11 schools have announced any increase in fees for the coming academic year. These increases range from $10 to $119. The average tuition fee now stands at 164% of the average tuition fee in 1939-1940, which was $378. As pointed out in the preceding section, however, student fees will provide only 20.1% of the cost of operating the medical schools during the forthcoming year.

900 to 999	6	..	7	..
1,000 and over	1	..	1	..
Totals	79	11	79	11

In table 26 the 90 medical schools and schools of the basic sciences in the United States and Canada have been arranged in groups according to the fees that will be charged resident students for the session 1953-1954. This table also gives comparable statistics for the year 1952-1953. The figures in this table represent one-fourth of the total fees charged students for the four years of the medical course, including tuition fees and minor charges such as those for matriculation, breakage, diploma, and graduation. Thirty-one schools in the United States make an additional charge for nonresident students. In 29 schools these charges range from $80 to $600. One school charges nonresident students an additional fee of $1,100 and another an additional fee of $2,130.

Cost of Attending Medical School

The schools were requested this year to estimate the cost to their students of attending medical school. They were requested to include in the estimates all essential costs such as tuition and other fees, books, equipment, travel, and living costs. Seventy-seven schools provided the data requested. The average minimum outlay was estimated at $1,682, with a high of $3,300, a median of $1,680 and a low of $733. Estimates of the average cost averaged $2,083, with a high of $4,500, a median of $2,000, and a low of $900.

When similar figures were requested of the schools three years ago the median minimum outlay was estimated at $1,473 as compared to $1,680 this year, and the median for the average outlay was $1,800 as compared to $2,000.

Scholarship and Loan Funds

This year for the first time the medical schools were requested to furnish information concerning the total amount of scholarship and loan funds available to their students from funds held by or directly controlled by the medical schools and/or their parent universities. The 62 schools that reported on scholarship funds had available an average of $12,014. The largest amount reported was $110,625, the lowest $300, and the median $7,500. Seventy-three schools reporting on loan funds had an average of $41,201 available, with a high of $500,000, a median of $41,201, and a low of $500.

These are by no means the sole sources of financial aid available to undergraduate medical students. Some state governments have scholarships for their own residents and in 12 states special subsidies are offered to students who will agree to practice in small towns or rural areas. Additional aid is provided through the Southern Regional Education Board whereby the governments of 11 Southern states have contracted with a group of Southern medical schools for the education of a certain number of their residents. Through the Western Governors' Conference, a similar compact has been developed by five Western states. A third regional education plan is being actively considered for the New England states, and three states, Vermont, New Hampshire and Maine, have already passed enabling legislation to facilitate the activation of such a plan.

Private and Governmental Medical Schools

The medical schools in the United States are listed in table 27 according to the nature of their ownership. There were no changes of ownership during the last year. Forty-one schools are owned by private nonprofit corporations exempt from federal taxation; 35 schools are owned by states and three by municipal governments.

Enrollments in the private schools during 1952-1953 totaled 14,517, or 52.4% of the total for the country. The enrollment in state and municipal schools was 13,171, or 47.6%. Both groups of schools have shown an increase in total enrollments in the last three years. The increase has been slightly greater proportionally in the government owned schools which in 1949-1950 enrolled 45.1% of all medical students as compared with 47.6% during 1952-1953.

Freshman students in private schools numbered 3,748, or 50.5% of the total, and 3,677, or 49.5%, in the state and municipal schools. There has been a gain in the past three years by the governmental schools of 1.9% of the total freshman students enrolled.

Statistics with respect to resident and nonresident student enrollment in state and municipal as compared with private schools are presented in the section on the geographic sources of freshman students. Budgets of state and municipal schools for 1953-1954 will total approximately $43,854,000 and for the private schools $43,550,000. For the government owned schools this represents an increase of $4,654,000 over a year ago and for the private schools an increase of $1,885,000. During the past three years the budgets of the state and municipal schools have increased approximately $12,854,000 while those of the private schools have increased by $7,000,000.

Tuition fees of state and municipal schools for residents of their own state will vary in 1953-1954 from $99 to $800, with a median of $406. For private schools, tuition fees will range from $508 to $1,291, with a median of $832.

Totals	79	11	79	11

In table 26 the 90 medical schools and schools of the basic sciences in the United States and Canada have been arranged in groups according to the fees that will be charged resident students for the session 1953-1954. This table also gives comparable statistics for the year 1952-1953. The figures in this table represent one-fourth of the total fees charged students for the four years of the medical course, including tuition fees and minor charges such as those for matriculation, breakage, diploma, and graduation. Thirty-one schools in the United States make an additional charge for nonresident students. In 29 schools these charges range from $80 to $600. One school charges nonresident students an additional fee of $1,100 and another an additional fee of $2,130.

Cost of Attending Medical School

The schools were requested this year to estimate the cost to their students of attending medical school. They were requested to include in the estimates all essential costs such as tuition and other fees, books, equipment, travel, and living costs. Seventy-seven schools provided the data requested. The average minimum outlay was estimated at $1,682, with a high of $3,300, a median of $1,680 and a low of $733. Estimates of the average cost averaged $2,083, with a high of $4,500, a median of $2,000, and a low of $900.

When similar figures were requested of the schools three years ago the median minimum outlay was estimated at $1,473 as compared to $1,680 this year, and the median for the average outlay was $1,800 as compared to $2,000.

Scholarship and Loan Funds

This year for the first time the medical schools were requested to furnish information concerning the total amount of scholarship and loan funds available to their students from funds held by or directly controlled by the medical schools and/or their parent universities. The 62 schools that reported on scholarship funds had available an average of $12,014. The largest amount reported was $110,625, the lowest $300, and the median $7,500. Seventy-three schools reporting on loan funds had an average of $41,201 available, with a high of $500,000, a median of $41,201, and a low of $500.

These are by no means the sole sources of financial aid available to undergraduate medical students. Some state governments have scholarships for their own residents and in 12 states special subsidies are offered to students who will agree to practice in small towns or rural areas. Additional aid is provided through the Southern Regional Education Board whereby the governments of 11 Southern states have contracted with a group of Southern medical schools for the education of a certain number of their residents. Through the Western Governors' Conference, a similar compact has been developed by five Western states. A third regional education plan is being actively considered for the New England states, and three states, Vermont, New Hampshire and Maine, have already passed enabling legislation to facilitate the activation of such a plan.

Private and Governmental Medical Schools

The medical schools in the United States are listed in table 27 according to the nature of their ownership. There were no changes of ownership during the last year. Forty-one schools are owned by private nonprofit corporations exempt from federal taxation; 35 schools are owned by states and three by municipal governments.

Enrollments in the private schools during 1952-1953 totaled 14,517, or 52.4% of the total for the country. The enrollment in state and municipal schools was 13,171, or 47.6%. Both groups of schools have shown an increase in total enrollments in the last three years. The increase has been slightly greater proportionally in the government owned schools which in 1949-1950 enrolled 45.1% of all medical students as compared with 47.6% during 1952-1953.

Freshman students in private schools numbered 3,748, or 50.5% of the total, and 3,677, or 49.5%, in the state and municipal schools. There has been a gain in the past three years by the governmental schools of 1.9% of the total freshman students enrolled.

Statistics with respect to resident and nonresident student enrollment in state and municipal as compared with private schools are presented in the section on the geographic sources of freshman students. Budgets of state and municipal schools for 1953-1954 will total approximately $43,854,000 and for the private schools $43,550,000. For the government owned schools this represents an increase of $4,654,000 over a year ago and for the private schools an increase of $1,885,000. During the past three years the budgets of the state and municipal schools have increased approximately $12,854,000 while those of the private schools have increased by $7,000,000.

Tuition fees of state and municipal schools for residents of their own state will vary in 1953-1954 from $99 to $800, with a median of $406. For private schools, tuition fees will range from $508 to $1,291, with a median of $832.

Vacancies in Instructional Staffs

The total numbers of full-time faculty positions that medical schools were unable to fill have been reported for the past four years. This year the schools were asked to indicate which of these vacancies are in newly created positions and which were positions budgeted for in the academic year 1952-1953. These figures are summarized in table 28.

The total number of unfilled positions was 283, the highest number since the 441 reported in 1949, and it exceeds by 88 the number of vacancies reported last year. The 120 vacancies on the staffs of preclinical departments was 16 more than last year but less than in the other three preceding years. It is of interest that 47, or more than one-third of these vacancies, represented newly created positions. Anatomy, pathology and physiology,, as in the preceding two years, had the greatest number of vacancies. Pathology departments had 34 unfilled posts; anatomy and physiology departments each had 18.

TAPLE 28.—*Number of New and Budgeted Unfilled Full Time Positions by Departments in the Medical and Basic Science Schools of the United States, 1953-1954*

	New	Budgeted 1952-1953	Number of Unfilled Positions
Preclinical departments			
Pathology	14	20	34
Anatomy	8	10	18
Physiology	7	11	18
Physiological Chemistry	4	12	16
Pharmacology	5	10	15
Microbiology	5	5	10
Bacteriology	4	5	9
Total	47	73	120
Clinical Departments			
Pediatrics	21	9	30
General Surgery	16	12	28
Psychiatry	9	16	25
Internal Medicine	11	12	23
Obstetrics and Gynecology	6	10	16
Radiology	5	8	13
Preventive Medicine and Public Health	5	5	10
Anesthesiology	3	..	3
Neurology	1	2	3
Ophthalmology	..	2	2
Orthopedic Surgery	..	2	2
Physical Medicine and Rehabilitation	1	1	2
Urology	..	2	2
Dermatology	..	1	1
Neurological Surgery	..	1	1
Otolaryngology	..	1	1
Otology	..	1	1
Total	78	85	163
Grand Totals	125	158	283

Clinical departments reported 163 unfilled billets, of which 78 or nearly half were new positions. The departments reporting the largest numbers of vacancies were pediatrics 30, general surgery 28, psychiatry 25, internal medicine 23, and obstetrics and gynecology 16. Pediatrics and surgery both had almost three times as many vacancies as in the preceding year. About two-thirds of the positions in pediatrics and almost half in surgery were in new posts. There were 30 schools that reported no vacancies in their full-time faculties.

The vacancies in newly created positions is of particular interest. These figures for the basic science departments probably result from the enlargement of these staffs made necessary by expansion of student enrollments; for the clinical departments they reflect the increasing tendency in recent years to employ full-time teachers, especially in the major clinical disciplines.

New Medical Schools

There have been several developments of importance during the past year with respect to the establishment of new medical schools and the expansion of schools of the basic medical sciences to full four year medical schools. Two new schools, the University of Puerto Rico School of Medicine and the University of British Columbia School of Medicine, had classes enrolled in the first three years of the medical school course during the past academic year and during the coming academic year will have students enrolled in all four classes. These schools will graduate their first classes in June, 1954. The University of North Carolina, which is expanding to a four year school, enrolled its first third year class during the past year, will have a fourth year class enrolled in 1953-1954 and will graduate its first class in June, 1954.

With respect to the eligibility of the graduates of these schools for internships during the year 1954-1955, the Council has adopted the following statement:

> ### ELIGIBILITY OF 1954 GRADUATES OF NEW MEDICAL SCHOOLS FOR INTERNSHIPS
>
> The Council on Medical Education and Hospitals has voted that students who will graduate from the University of North Carolina School of Medicine, the University of Puerto Rico School of Medicine and the University of British Columbia School of Medicine in 1954 will be considered as if they had graduated from an approved medical school. Hospitals approved for intern training will not lose their approved status if they accept these students for internships.
>
> The development of these three schools of medicine has been followed closely by the Council. In accordance with long standing policy, however, approval is not granted to any medical school until representatives of the Council survey the school after instruction has been instituted in all four years of the medical school course. The first senior classes at these medical schools will not be enrolled until the fall of 1953. Inspection of these schools, therefore, cannot be carried out in time to include the findings of the surveys in the 1953 Educational Number of THE JOURNAL which will be used by hospitals for determining whether applicants for internship are graduates of an approved medical school. If these three schools are included in the Council's approved list in 1954, the work of all students in good standing at the schools at the time of the Council's representatives survey the schools will be fully accredited.

Another new school, the University of California at Los Angeles, which admitted its first freshman class in the fall of 1951, will have freshman, sophomore, and junior classes enrolled during the coming year. The University of Miami School of Medicine admitted its first freshman class in the fall of 1952 and during the coming academic year will have both a freshman and a sophomore class enrolled.

Statistics for these new schools do not appear in the various tables included in this report. By custom the Council includes in this report only statistics from approved medical schools. No medical school is eligible for consideration for admission to the list of approved medical schools until its full four year program is in operation.

The University of Mississippi, which is expanding from a school of the basic medical sciences to a four year medical school, has made substantial progress during the past year in the construction of a new medical school building and university hospital at Jackson. It is tentatively expected that a junior class will be enrolled in the fall of 1955. Construction of a new medical school building and hospital has also been started at West Virginia University, which is also expanding to a four year school; however, no date has been set for enrollment of a third year class.

The University of Missouri, which received an appropriation of 6 million dollars in 1952 to enable it to expand its basic science school to a four year school at Columbia, is proceeding actively with plans for the new physical plant. No date has yet been set for enrolling a third year class.

Yeshiva University in New York City, which announced two years ago its intention of developing a medical school, has named the school the Albert Einstein College of Medicine and is proceeding actively with plans for construction that it is hoped can be initiated in the fall of 1953. It is hoped that the first freshman class can be enrolled in the fall of 1955.

During the spring of 1953 the Florida legislature provided 5 million dollars as an initial appropriation for the development of a medical school by the University of Florida at Gainesville.

In Kentucky, interest in developing a medical school under the auspices of the University of Kentucky in Lex-

TABLE 29.—*Foreign Medical Schools*

List Prepared by the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges

On the basis of information presently available, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges are of the opinion that medical institutions and medical organizations in the United States would be justified in considering current and past graduates of the following foreign medical schools on the same basis that they consider graduates of approved medical schools in the United States. This list is not final and will be supplemented as information is compiled for other schools.

Belgium

Free University of Brussels Faculty of Medicine
(Université Libre de Bruxelles Faculté de Médecine)
Catholic University of Louvain Faculty of Medicine
(Université Catholique de Louvain Faculté de Médecine or Katholieke Universiteit te Leuven)
University of Ghent Faculty of Medicine
(Universiteit te Gent Faculteit der Geneeskunde, or Université de Gand Faculté de Médecine)
University of Liège Faculty of Medicine
(Université de Liège Faculté de Médecine)

Brazil

University of São Paulo Faculty of Medicine
(Universidade de São Paulo Faculdade de Medicina)

China

Peiping Union Medical College

This recommendation applies to all those graduates who were granted the degree of Doctor of Medicine from the date when the first degrees were conferred in 1921 until and including the class of 1943. The education of students in the last class, that of 1943, was interrupted by World War II; therefore, some students finally completed their studies as late as 1949. However, their diplomas were issued as of the class of 1943. Following the Communist conquest of China the name of this school was changed to the China Union Medical College. The recommendation does not apply to this school.

Denmark

University of Copenhagen Faculty of Medicine
(Kobenhavns Universitet Laegevidenskabelige Fakultet)

Finland

University of Helsinki Faculty of Medicine
(Helsingfors Universitet Medicinska Fakulteten)
Medical Faculty Turku University
(Turun Yliopiston Laaketieteellinen Tiedekunta)

Lebanon

American University of Beirut School of Medicine

Netherlands

University of Amsterdam Faculty of Medicine
(Universiteit van Amsterdam Geneeskunde Faculteit)
State University of Groningen Faculty of Medicine
(Rijks-Universiteit te Groningen Geneeskunde Faculteit)
State University of Leiden Faculty of Medicine
(Rijks-Universiteit te Leiden Faculteit der Geneeskunde)
State *University of Utrecht Faculty of Medicine*
(Rijks-Universiteit te Utrecht Faculteit der Geneeskunde)

Norway

University of Oslo Faculty of Medicine
(Kongelige Frederiks Universitet Medisinske Fakultet)

Sweden

Royal Charles University Medical Faculty, Lund
(Kungl. Karolinska Universitetet Medicinska Fakulteten)
Charles Medico-Surgical Institute, Stockholm
(Karolinska Mediko-Kirurgiska Institutet)
Royal University of Uppsala Medical Faculty
(Kungl. Universitetet i Uppsala Medicinska Fakulteten)

Switzerland

University of Basel Faculty of Medicine
(Universität Basel Medizinische Fakultät)
University of Bern Faculty of Medicine
(Universität Bern Medizinische Fakultät)
University of Geneva Faculty of Medicine
(Université de Genève Faculté de Médecine)
University of Lausanne Faculty of Medicine
(Université de Lausanne Faculté de Mèdecine)
University of Zurich Faculty of Medicine
(Universitat Zurich Medizinische Fakultät)

The recommendation with respect to the following medical schools in Switzerland applies only to those graduates of Swiss medical schools who hold the Swiss Federal Diploma issued by the Federal Department of the Interior (Eidgenoissisches Department Des Innern, Département Féderal de L'Intérieur) and obtainable only by Swiss citizens who hold the Certificate of Medical Studies (Akademische Zeugnis, Certificat d'Études Médicales), or who hold one of the following certificates which the Swiss Universities issue to those, not citizens of Switzerland, who complete a course of study and pass examinations equivalent to those taken by Swiss citizens in qualifying for the Swiss Federal Diploma:

University of Basel—Academic Certificate on passing the medical examination for physicians (Akademische Zeugnis uber die bestandene Fachprufung fur Ärzte)

University of Bern—Medical diploma on passing examination for medicine (Aerztliches Fakultats diplom uber die bestandene Fachprufung für Ärzte).

University of Geneva and University of Lausanne—Certificate of Medical Studies (Certificat d'Études Médicales).

University of Zurich—Medical diploma for Foreigners (Medizinisches Diplom für Ausländer).

United Kingdom

England

University of Birmingham Faculty of Medicine
University of Bristol Faculty of Medicine
University of Cambridge Faculty of Medicine
University of Durham Medical School, Newcastle-upon-Tyne
University of Leeds Faculty of Medicine
University of Liverpool Faculty of Medicine
University of London †
University of Manchester Faculty of Medicine
University of Oxford Faculty of Medicine
University of Sheffield Faculty of Medicine

Northern Ireland

Queen's University of Belfast Faculty of Medicine

Scotland

University of Aberdeen Faculty of Medicine
University of *Edinburgh Faculty of Medicine*
University of Glasgow Faculty of Medicine
University of St. Andrews Medical School, St. Andrews and Dundee

Wales

Welsh National School of Medicine, University of Wales, Cardiff

The recommendation applies only to those physicians trained in the United Kingdom who *hold medical degrees from the universities listed.* The recommendation does not apply to those physicians who received their medical training at these universities or their affiliated hospital medical schools but who did not complete the work for the degree and who obtained their qualifications only through the examinations of the licensing corporations of the United Kingdom.

---

† Work for the medical degree of the University of London is offered at the following hospital medical schools:
Charing Cross Hospital Medical School
Guy's Hospital Medical School
King's College Hospital Medical School
London Hospital Medical School
Middlesex Hospital Medical School
Royal Free Hospital School of Medicine
St. Bartholomew's Hospital Medical College
St. George's Hospital Medical School
St. Mary's Hospital Medical School
St. Thomas' Hospital Medical School
University College Hospital Medical School
Westminster Hospital Medical School

ington continues, and the legislative research commission is preparing a report on this project for submission to the 1954 session of the legislature.

There has been no action with respect to establishing new medical schools in New Jersey, Massachusetts, and Connecticut, three states that have been giving serious study to the possibility of establishing schools within recent years. In the New England states, however, considerable discussion is being given to a New England regional higher education plan, which would include a medical school. Vermont, Maine and New Hampshire have already passed enabling legislation for participation by those states in such a plan.

Foreign Medical Schools

In February, 1950, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges first published a list of foreign medical schools whose graduates they recommend for consideration on the same basis as graduates of approved medical schools in the United States. The list is intended as a guide for institutions and organizations in this country who deal with foregn medical graduates and also as an aid to American students who plan to study medicine abroad.

Data on which this list is based are provided largely by American medical educators who, while on trips abroad, have volunteered to visit and report on foreign medical schools. In evaluating these data and developing the list, valuable assistance has been given by the Committee on Foreign Medical Credentials. This committee, established to advise the Council, is made up of representatives of a large number of private and governmental agencies which are concerned with medical education, medical licensure, and the problems of foreign trained physicians.

It has been emphasized that this list is a tentative one to which additional schools may be added as data are received that justify their inclusion. Hence, the absence of a school from the list does not necessarily imply that its educational program is unacceptable. It has not been possible to develop a satisfactory program for the evaluation of certain formerly reputable foreign schools whose programs are known to have deteriorated as a result of the war and subsequent events. Evaluation of the credentials of graduates from schools not named in the list is, therefore, a responsibility of those other agencies and organizations to whom such individuals apply for recognition. The Councils can offer no advance statement concerning schools which might in the future be included in the list.

Table 29 names the 50 schools now included in the list. The only change made during the past year was the inclusion of the Peiping Union Medical College. This school was renamed the China Union Medical College following the communist conquest of China and the recommendation does not apply to graduates of this latter school. The list is now accepted by 26 of the state licensing boards and by the National Board of Medical Examiners.

American Students In Foreign Medical Schools

Statistics were reported last year on the number of American students enrolled in foreign medical schools. The foreign schools were requested to furnish similar information again this year, and additional data were secured with the assistance of the Department of State and the National Selective Service System.

Figures for the 188 foreign schools from which data were secured are summarized in table 30. Countries are listed in order of the number of American students enrolled. A total of 1,734 students from the United States were enrolled in 72 foreign medical schools located in 22 different countries. As was true a year ago, the countries with the largest numbers of American students were Switzerland, Spain, and Italy. Other countries having more than 50 such students are Mexico, Germany, France, Belgium, the Dominican Republic, Austria, and the Netherlands. The footnote to table 30 indicates that about one-third of the entire student group are from Puerto Rico.

Table 31 recapitulates the figures for 1951-1952 and 1952-1953. Figures are available this year for 4 more countries and 13 more schools than last year. The number of foreign schools reporting American students has decreased by 6, but the total number of such students reported has increased by 613. The numbers of Puerto Rican students enrolled abroad has increased from 303 to 579.

TABLE 30.—*Distribution of American Students In Foreign Medical Schools, 1952-1953*

* Included in total number of students are the following figures for students from Puerto Rico supplied by the Selective Service System.

Spain	386
Mexico	126
Dominican Republic	38
Cuba	10
Chile	9
France	5
Switzerland	2
Uruguay	2
Argentina	1
	579

Table 32 lists, in order, the schools with the largest numbers of American enrolled. This table is not comparable to the similar one prepared last year, since some schools for which data were available last year, for example, the University of Madrid, which had 150 American students, did not reply this year and others like the University of Lausanne, which this year reported 110 students, provided no data last year. The four schools with more than 100 American students enrolled were, in order, University of Geneva (180), University of Rome (150), National University of Mexico (113), and University of Lausanne (110).

TABLE 31.—*Distribution of American Students in Foreign Medical Schools, 1951-1953*

	No. of Countries	No. of Schools	No. of Replies	Schools with American Students	Total No. of Students
1951-1952............	31	170	124	78	1,121*
1952-1953............	35	188	137	72	1,731†

* Includes 803 students from Puerto Rico studying in 8 countries reported by Selective Service System.

† Includes 579 students from Puerto Rico studying in 9 countries reported by Selective Service System.

Figures which were received on the distribution of students by classes appear in table 33. In this group of 614 students, 70% are enrolled in the first three classes. Information is not available to explain, with certainty, the fact that the largest number of students are enrolled in second year classes. However, since a large portion of the first two years in many foreign medical schools is devoted to subjects which are usually included in premedical courses in this country, it is likely that many American students, by obtaining credit for premedical studies completed in the United States, have been able to gain admission to advanced standing. It is possible, therefore, that a substantial proportion of the second year group are students who were first admitted to foreign schools during the past academic year.

TABLE 32.—*Foreign Medical Schools with Largest Numbers of American Students Enrolled, 1952-1953*

Name of University	American Students Enrolled	Total Enrolment
Geneva (Switzerland)	180	728
Rome (Italy)	156	.....
National University (Mexico)...........	113*	6,000

Galway (Ireland)	19	187
Munich (Germany)	15	1,665
Basel (Switzerland)	15	540
Montpellier (France)	11	1,250
Athens (Greece)	11	1,800

* Includes 95 students from Puerto Rico.

The caution which was voiced in this section last year will bear repetition. Correspondence received by the Council from American students enrolled in foreign medical schools and information received from other sources indicate that many of these students hope that, at the end of a year or two, they will be able to transfer to an American school. The likelihood of their being able to do so is small, not only because American schools are filled to capacity but also because differences in the organization of the curriculum of foreign schools make it difficult to fit such students into the programs of American schools.

Students who plan to study medicine abroad are also cautioned to determine whether or not the credentials which they will obtain will be recognized in this country. It is apparent that many of these students have not fully informed themselves concerning the educational standards of foreign schools. While there are many such schools whose excellence is rather widely recognized in the United States, there are others whose credentials may not be accepted by the licensing authorities. Students who are planning to study medicine abroad are therefore urged to communicate directly with the licensing boards of states where they hope to practice and to determine in advance of enrollment whether or not the credentials which they will receive are acceptable.

TABLE 33.—*Enrollment of American Medical Students by Classes, 1952-1953*

* Only some of the schools supplied this information; therefore, the totals within some countries differ from those found in table 30.

The Council has prepared a compendium of information on foreign medical education and the status of foreign medical credentials in the United States.[6] Reprints of this publication will be furnished on request, without charge.

Postgraduate and Continuation Courses for Physicians

The Council on Medical Education and Hospitals has published semiannually in THE JOURNAL a listing of postgraduate and continuation courses for physicians for the past 17 years. The opportunities presented in these listings include a wide variety of fields in clinical medicine and the basic sciences. The courses offered are for variable periods. With the exception of the formal basic science courses, these courses are not usually intended to prepare physicians for certification by the American boards in the specialties. Some opportunities are offered, however, for review work in preparation for the examinations of the specialty boards. The current listing was published in the June 13, 1953, issue of THE JOURNAL.

---

[6] To be published.

This section is devoted to an analysis of the courses offered during the period July 1, 1952, to June 30, 1953. Brief mention is also made of some of the recent developments in postgraduate education. The statistical summaries are divided into three groups: short review courses of less than five days, courses of five days' duration or longer and, lastly, a group including clinical conferences, graduate assemblies, seminars, study, and circuit courses. Comparable figures are shown for the preceding seven years.

RECENT DEVELOPMENTS

Several institutions introduced new subjects this year. The American Diabetes Association, Inc., of New York conducted a four day program in Toronto on "Diabetes and Basic Metabolic Problems." Applications for this course exceeded the facilities available. A course in legal medicine and the elements of medical-legal litigation was given by the University of Texas Medical Branch at Galveston. The University of Buffalo Medical School presented a two day course for physicians on "The Laboratory in Clinical Diagnosis," designed to keep the practitioner up-to-date on developments in the laboratory sciences and to improve his diagnostic accuracy. The course included discussions of the basic physiology and biochemistry involved in laboratory diagnosis, evaluation of tests, and the interpretation and demonstration of selected procedures. The Extension Division of the University of California at Los Angeles was able to utilize the results of six years of research experience by the engineering department to present a six week's course in "Prosthetics." This course was open to occupational and physical therapists and prosthetists as well as physicians and was repeated a number of times in order to accommodate groups from various regions throughout the country.

Programs in general practice increased throughout the country. The Illinois Academy of General Practice sponsored a series of courses for its members at 10 widely separated centers throughout the state during March and April. Several of the medical schools in Chicago participated in this program. The Frank E. Bunts Educational Institute of the Cleveland Clinic Foundation inaugurated a two day general practice program in May. This course was sponsored jointly by the Institute and the Cuyahoga County Chapter of the American Academy of General Practice. Other organizations also added general practice refresher courses to their programs.

In many programs an effort in the direction of more individualized teaching methods was noted. The Los Angeles County Heart Association offered "Postgraduate Preceptorships in Cardiology" for the general practitioner. These preceptorships involved 12 sessions in which the physician-student and his preceptor discussed and interpreted the electrocardiograms and learned the latest methods of diagnosis and treatment while observing patients over a period of several visits. The new program of the Commission on Graduate Education of the Medical Society of the State of Pennsylvania included panel discussions, clinics, and round-table discussions.

Various postgraduate teaching techniques have been employed for the convenience of the practicing physician. Telephone seminars, consisting of panel discussions emanating from a central point to local county medical society groups throughout the state, were utilized by the state medical societies of Indiana, Kentucky, Pennsylvania, and Texas. Recordings of the Indiana program were used in Arizona for one of the programs of the state medical association. Recordings are also being developed as a mode of postgraduate communication by several other groups. Televised postgraduate programs of short duration were given by the universities of Alabama, Kansas, and Maryland. In all cases the program was televised intramurally, and surgery was the major subject presented. Plans are under consideration by a number of other institutions for the use of television in postgraduate programs. The American Cancer Society is planning a series of forty color television programs, all designed for the practicing physician. More and more medical schools are endeavoring to take their courses to the doctor in lieu of his coming to school. This is particularly true for the general practice refresher programs.

The Tennessee State Medical Association has just completed a circuit course on "Internal Medicine and Circulatory Diseases." Ten sessions were held in each of 50 teaching centers. In California, the state medical association utilized outlying centers for programs that in each case were presented by teams recruited from the faculties of the five medical schools of the state. Faculty members of the University of Colorado School of Medicine conducted one or two day postgraduate sessions at regular intervals in strategic centers. Similar programs were offered in Michigan, North Carolina, Pennsylvania, and Wisconsin.

In those states where ample clinical facilities are not available, medical schools in adjacent states have cooperated by sending teaching teams into these areas for one or more postgraduate programs. In this way, the physician in these states can obtain postgraduate training in or near his home community. The University of Utah School of Medicine sent a team to Arizona while the University of Colorado supplied teams in New Mexico and Wyoming as a part of its extension program. The University of Kansas School of Medicine presented an extensive program designed specially for physicians in nearby cities in Missouri. Several other medical schools contributed to the postgraduate needs of their region outside their own state, either by extension programs or special intramural programs for the physicians of these neighboring states.

The many different organizations and institutions who are engaged in postgraduate education have recognized the need for joint action or coordination in the interest of economy and efficiency of their various activities. In Massachusetts this has led to the development of the Postgraduate Medical Institute, which is sponsored by the three medical schools in Boston, the state medical society, the state health department, and representatives of a number of voluntary health agencies. By pooling resources and ideas, these organizations have been able to coordinate effort and to present a number of jointly sponsored programs. The initial experience with this program has proved successful, and it is planned to expand it for the coming year.

Coordination of the efforts of a number of interested groups is illustrated again by the course in "Treatment of Emergencies" conducted by the Southwestern Medical School of the University of Texas in association with the Texas Medical Association, Texas Academy of General Practice, the Dallas Southern Clinical Society, and the Postgraduate School of the University of Texas. Michigan and Wisconsin have been operating their programs on this basis for some time. Other states are considering adopting a similar pattern.

Recognizing the constant growth of interest and activity in the whole field of postgraduate medical education, the Council has been engaged for the past year in a comprehensive study of this field. This has involved personal visits to all of the major organizations and institutions involved in this kind of work, and first hand observation of a number of programs in action. Material derived from this survey is being supplemented by written data and information derived from a questionnaire study. It is hoped that the results of this study will be ready for publication some time early in 1954.

ANALYSIS OF COURSES OFFERED, 1952-1953

Courses of Less Than Five Days' Duration.—During 1952-1953, 30 states and the District of Columbia provided opportunities of less than five days' duration for physicians desiring to continue postgraduate study in or near their home communities. There were 324 courses offered. Table 34 lists these states and the number of courses given in each state. Thirty-eight subjects were covered. Table 35 lists the subjects and the number of courses given in each subject. The attendance numbered 9,452.

The courses varied in length from sessions of one hour or a series of five or more lectures to four days full time and consisted of organized courses, clinics utilizing hospital patients, lectures, and demonstrations. Of the 324 courses offered, 40 were four day courses, 121 were three day courses, 122 were two day courses, and 21 were given in one full day. The remainder of the courses were reported by lectures, sessions, or hours. Forty medical schools participated in 253 of the courses offered. Other sponsoring agencies included hospitals in 44 instances and the Medical Department of the Army, special societies, and a graduate school in the remainder of the courses.

These opportunties were offered in every month except August. Sixteen courses were offered continuously and 21 quarterly. The instructors were chosen from the faculties of medical schools and from physicians practicing in the state. Medical school instructors participated exclusively in 71 courses and 66 were given by physicians in the state, while combinations of medical school instructors and physicians located in the state and elsewhere gave the remainder.

These opportunities were of the type that would interest all practicing physicians. None were given for specialists only. The courses were both clinical and didactic or both. There were 74 courses offered devoted exclusively to didactic instruction. The fees ranged from $5 to $200. The majority of the fees were less than $50. In 42 instances no fee was charged.

The increasing interest in courses of less than five days' duration was evidenced in that there were 128 more opportunities for this type of training than given in the comparable previous period. The attendance exceeded that of the session 1951-1952 by 1,998. The total attendance reported for 295 of the 324 courses offered was 9,452. Scheduled courses in this group that were canceled numbered 43.

Courses of Five Days' Duration or Longer.—In centers where ample clinical facilities were available 805 postgraduate courses of five days' duration or longer were offered in 30 states and the District of Columbia during 1952-1953. The states that provided these opportunities and the number of courses that were given in each state are recorded in table 36.

The 805 programs varied from refresher courses of five or more days to intensive courses extending over several months. Courses in 43 subjects were given. Table 37 lists the subjects covered. For this type of training the total attendance was 23,793.

In 115 instances courses of five days' duration were offered. There were 374 courses given that were of more than five days' duration but less than one month, 166 courses ranged from one to three months, and in 150 instances the courses varied in length from four months to three years. Included among the 150 courses were 26 eight month courses, 14 covering 9 months, 35 one year in length, and one of three years. In 36 instances courses were arranged to suit the convenience and the time of the applicant.

Medical school facilities were used for 658 courses, hospitals for 46, and clinics for 6. In many instances two or all three of these sources were used in presenting an individual course. Hotel and other facilities were used for 30 courses. For 65 courses, the type of facility used was not specified. Instruction was both didactic and clinical for 452 courses, didactic only for 202, clinical only for 41, laboratory and didactic for 30, and unspecified in 80.

The faculties of medical schools served as instructors in 560 courses. Additional instructors were specialists in their field, chosen mainly from physicians residing within the state in which the course was given but including as well physicians from outside the state. Courses were offered during every month from July, 1952, through June, 1953. In 170 instances they were arranged to suit the convenience of the physician students. Forty-three courses were offered continuously and nine quarterly. There were 43 courses whose enrollment was limited to specialists only. Fees ranged from $5 to $1,040. For 54 courses no fee was charged.

Forty-nine medical schools sponsored this type of training during 1952-1953. Other agencies participating included hospitals, special societies, state and county medical societies, health departments, graduate schools of medicine, and the government agencies.

Attendance for the 805 courses totaled 23,793. By comparison with the previous years, there was a marked decrease in the number of courses offered while the attendance exceeded the previous year by 6,282. Scheduled courses that were cancelled totalled 198.

Clinical Conferences, Graduate Assemblies, Study and Circuit Courses, and Seminars.—In 30 states and the District of Columbia, 253 clinical conferences, graduate assemblies, study and circuit courses and seminars were held during 1952-1953. The states that presented this type of training are listed in table 38. Twenty-nine subjects were covered; table 39 lists the subjects and the number of programs offered. Contributing agencies were speakers' bureaus, medical schools, state and county medical societies, state health departments, and special societies. This type of training varied in length from one day sessions to two weeks for conferences, assemblies, seminars, and study courses. In four states, circuit courses were held. The facilities of hospitals, clinics, medical schools, and hotels were used. Instruction was both didactic and clinical. Instructors included members of medical school faculties and physicians practicing in the state in which the training was given as well as from out of state. These opportunities were offered in every month. The fees ranged from $5 to $250. In 27 instances no fee was charged. The attendance numbered 31,363. In this type of training there was an increase of 122 in the number of opportunities provided, but the total attendance as compared with the previous year showed a decrease of 9,607. Two programs were canceled.

SUMMARY

Some form of continuation study for practicing physicians was reported as being provided during 1952-1953 in all but 10 states. Table 40 summarizes for the three groups the number of courses given, the number for which attendance was reported, and the total attendance, together with comparable figures for seven previous years. While the total number of programs offered during 1952-1953 decreased by 487 as compared with the previous year, the total attendance showed only a decrease of 1,327. The figures reported show that the attendance at many of the individual courses increased in numbers. Further analysis will show that the decrease occurred only in the group of opportunities for training in courses of five or more days' duration.

A study of table 40 reveals some interesting trends. The number of courses offered rose rapidly following World War II, reaching a peak of 1,800 in the 1947-1948 period. A sharp and continuing decline then occurred, swinging upward again in 1950-1951. In 1951-1952 the trend was again upward, reaching the all time high in a seven year period. The figures for 1952-1953 were again downward and appear to show a greater interest in the shorter opportunities provided as contrasted with the more intensive courses.

A similar review of the attendance figures shows a parallel trend in the immediate postwar years, but with a marked drop occurring in the 1950-1951 records even after the number of courses had again started to rise. The number of courses offered in 1952-1953 was the lowest figure in the past five years, although the attendance record does not reveal a comparable decline.

Medical education is a continuous process, and it is the responsibility of every physician to keep abreast of advances in medicine. Data presented in this section is evidence that the physicians of the country recognize this responsibility. Institutions and agencies are continuing to attempt to provide opportunities of current interest. The popularity of programs developed is revealed by the attendance records. However, the variables in type, length and geographical location is another important factor to be given consideration by those currently giving courses or others planning programs.

APPROVED MEDICAL SCHOOLS IN THE UNITED STATES

ALABAMA

Birmingham

Medical College of Alabama, 620 S. 20th St., Zone 5.— Established in 1943 as a division of the University of Alabama. Located in Birmingham in 1944. In 1945 assumed title to Jefferson Hospital and Hillman Hospital, Birmingham. The Medical College of Alabama cares for all indigent patients of the county, maintenance of which is paid to the university on a per diem basis by the county. In 1943 the appropriation included one million dollars for the building of a new medical school which was completed and occupied in the Fall of 1951. With the increased facilities of this new building, the entering class of 1951 was increased to 80 students. First instruction in the Medical College of Alabama started June 4, 1945, with a junior class and this class was graduated in October 1946. On Oct. 8, 1945, the School of the Basic Medical Sciences on the University Campus, established in 1920, and its faculty, were absorbed into the new Medical College of Alabama. The medical college is coeducational. Minimum requirements are three years of college work. Tuition is as follows: for legal residents of Alabama $400 per academic year plus incidental fees of $45. Nonresidents of the state are charged an additional $250 each session. The registration for the 1952-1953 session was 271, graduates 54. The last session began for all classes on Sept. 19, 1952. The session ended for all classes on May 30, 1953. The next session for all four classes will begin Sept. 17, 1953, and will end on May 29, 1954. The dean is James J. Durrett, M.D.

ARKANSAS

Little Rock

University of Arkansas School of Medicine, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The curriculum covers four sessions of nine months each. Entrance requirements are three years of collegiate work. The B.S. degree is conferred at the end of the second year. The fees for the four years for residents of Arkansas are $380 a year; enrollment is restricted to residents of Arkansas. The registration for the 1952-1953 session was 324, graduates 78. The last session began Sept. 22, 1952, and ended June 15, 1953. The next session will begin Sept. 21, 1953 and will end June 14, 1954. The dean is Hayden C. Nicholson, M.D.

CALIFORNIA

Loma Linda—Los Angeles

College of Medical Evangelists, Loma Linda; Boyle and Michigan Ave., Los Angeles 33.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. Coeducational since organization. Three years of college work are required for admission. The freshman, sophmore, and junior years consist of nine month academic sessions and the senior year will have in addition to the nine month session a four weeks' clinical clerkship during the summer between the junior and senior years. A 12 month internship in an approved hospital is required. The yearly tuitions, including fees, are respectively, $1,292.00, $1,280.50, $1,286.25, $1,303.75. The registration for 1952-1953 was 377; graduates 1953-A, 98; 1953-B, 93. The last session for freshman and sophmore students began on Aug. 31, 1952, and ended June 5, 1953, respectively. The junior session began on Sept. 7, 1952, and ended June 6, 1953. The senior session began June 8, 1952, and was completed June 7, 1953. The next session for freshman and sophmore students will begin Aug. 30, 1953, junior students Sept. 13, 1953, and senior students began June 8, 1953, and will end June 4, 1954, for the freshman and sophomore classes, June 5, 1954 for junior students, and June 6, 1954 for seniors. The president is Walter E. Macpherson, M.D., Los Angeles. The dean is Harold Shryock, M.D., Loma Linda.

Los Angeles

University of Southern California School of Medicine, 3518 University Ave., Zone 7.—Organized in 1895 as the University of Southern California College of Medicine. First class graduated in 1899. In 1908 it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. Entrance requirements are three years of college work. An internship is required for graduation. Coeducational since organization. Annual fees amount to approximately $865. The registration for 1951-1952 was 275; graduates, 67. The last session began Sept. 15, 1952, and ended June 13, 1953. The next session will begin Sept. 21, 1953, and will end June 12, 1954. The dean is Gordon E. Goodhart, M.D.

San Francisco

University of California School of Medicine, Medical Center, San Francisco 22.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California at Los Angeles became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The medical course consists of four academic years, each containing two semesters of sixteen weeks each. The fees are $320 per academic year. Nonresidents are charged $250 additional each year. The registration for the 1952-1953 session was 301; graduates 72. The last session began Sept. 22, 1952 and ended June 18, 1953. The next class will begin Sept. 14, 1953 and will end June 17, 1954. The dean is Francis Scott Smyth, M.D.

Stanford—San Francisco

Stanford University School of Medicine, Stanford, 2398 Sacramento Street, San Francisco.—The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry and physiology are located on the campus at Stanford, which is thirty miles southwest of San Francisco adjoining the city of Palo Alto. The post office is Stanford. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. Three years of collegiate work are required for admission. The quarter plan is in operation. An internship is a requirement for graduation. The average fee for each of the four years is $780. The registration for 1952-1953 was 243, graduates 62. The last session for all classes began Sept. 29, 1952, and ended June 10, 1953. The next session will begin Sept. 28, 1953, and will end June 9, 1954. The acting dean is Windsor Cooper Cutting, M.D.

COLORADO

Denver

University of Colorado School of Medicine, 4200 East Ninth Avenue., Zone 7.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine were merged Jan. 1, 1911. Coeducational since organization. The entrance requirements are three years of collegiate work. The fees average $525 per academic year. Nonresidents are charged $2,130 additional each year. The registration for 1952-1953 was 313; graduates 73. The last session began Sept. 22, 1952, and ended June 6, 1953. The next session will begin Sept. 18, 1953, and will end June 5, 1954. The Director of the Medical Center is Francis R. Manlove, M.D.; the dean is Robert C. Lewis, Ph.D.

CONNECTICUT

New Haven

Yale University School of Medicine, 333 Cedar Street, Zone 11.—Initial organization of the School of Medicine was completed in 1812 following passage of a bill by the Connecticut General Assembly in 1810 granting a charter for "The Medical Institution of Yale College," to be conducted under joint supervision of the College and the Connecticut State Medical Society. Formally opened in 1913; first degrees conferred 1814. In 1884, with the approval of the Medical Society, the original charter was amended to place the school definitely in the control of the College as the Medical School of Yale College. The name Yale College was changed to Yale University in 1887 and the name of the Medical School was automatically changed. The present name was adopted in 1918. Coeducational since 1916. The requirements for admission are three years of college work. The fees average $829 per academic year. The registration for 1952-1953 was 290; graduates 64. The last session began Sept. 24, 1952 and ended May 30, 1953. The next session will commence Sept. 23, 1953 and will end May 29, 1954. The dean is Vernon W. Lippard, M.D.

DISTRICT OF COLUMBIA

Washington

Georgetown University School of Medicine, 3900 Reservoir Road, N.W., Zone 7.—Organized in 1851. First class graduated in 1852. The degree of Bachelor of Arts or Bachelor of Science or its equivalent from an approved college of arts and sciences is required for admission of non-veterans, but veterans may be admitted with a minimum of 90 semester hours of credit. The fees average $965 per academic year. Registration for 1952-1953 was 441; graduates 95. The last session for freshmen started Sept. 15, 1952, and ended May 23, 1953; the sophomore class started Sept. 15, 1952, and ended May 23, 1953; the junior class started Aug. 27, 1952, and ended May 15, 1953, and the senior class started on May 26, 1952, and ended on May 23, 1953. The date of graduation was June 8, 1953. The next session for freshmen and sophomores will begin Sept. 14, 1953, and end May 22, 1954; the juniors will be in session from Aug. 26, 1953, to May 14, 1954; the senior session began May 25, 1953, and will end May 22, 1954. The date of graduation will be June 7, 1954. The dean is Francis M. Forster, M.D. The regent and dean of students is Rev. Thomas J. O'Donnell, S.J.

George Washington University School of Medicine, 1335 H Street, N.W., Zone 5.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name "National Medical College." Classes were graduated in 1826 and in all subsequent years except in 1834-1838 and 1861-1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904 by an Act of Congress the title of George Washington University was granted to the institution. Coeducational since 1884. Three years of college work are required for admission. The tuition is $850 per academic year. Registration for 1952-1953 was 347; graduates 92. The last session began Sept.

15, 1952, and ended May 27, 1953. The next session will begin Sept. 21, 1953, and will end on June 9, 1954. The dean is Walter A. Bloedorn, M.D.

Howard University College of Medicine, 520 W Street, N.W., Zone 1.—Chartered in 1867. Organized in 1869. The first class was graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The minimum requirements are four years of collegiate work, but practically the bachelor's degree. The course covers four years of 33 weeks each. The fees are respectively: $526.75; $516.75; $486.75; $502.25. The registration for 1952-1953 was 289; graduates 67. The last session began Sept. 22, 1952, and ended June 5, 1953. The next session will begin Sept. 21, 1953, and will end June 4, 1954. The dean is Joseph L. Johnson, M.D.

GEORGIA

Atlanta

Emory University School of Medicine, 36 Butler St.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878) taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the School of Medicine of Emory University in 1915. Three years of collegiate work are required for admission. The course of study is four academic years; 36 weeks each in the first and second year; 40 weeks each in the third and fourth years. The fees for each of the four academic years are $800. The registration for 1952-1953 was 286; graduates 73. The last session for freshmen and sophomores began Aug. 28 and Sept. 2, 1952, and ended June 6, 1953. The last session for juniors and seniors began Aug. 4, 1952, and ended June 6, 1953. The next session for freshmen and sophomores will begin Aug. 27 and Sept. 1, 1953, and will end June 5, 1954. The next session for junior and senior classes will begin Aug. 3, 1953, and will end June 5, 1954. The dean is Richard Hugh Wood, M.D.

Augusta

Medical College of Georgia, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. On Jan. 18, 1950 it became the Medical College of Georgia. Property transferred to the university in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. Three years of college work are required for admission. Fees for 1953-1954, $390.00 per academic year for residents of Georgia, non-residents, $690.00. Only bona fide residents of Georgia admitted (with exception of A. S. T. and V-12 Program students during World War II). The registration for the 1952-1953 session was 314; graduates 81. The 1953-1954 session for the fourth year class will begin Sept. 10, 1953, and end June 5, 1954; the first, second and third year classes will begin Sept. 17, 1953, and end June 5, 1954. The president is Edgar R. Pund, M.D.

ILLINOIS

Chicago

Chicago Medical School, 710 South Wolcott Ave.—Founded in 1912 as the Chicago Hospital College of Medicine. In 1919 the name of the institution was changed to the Chicago Medical School. The school moved from its former location to its present site in the Medical Center in 1930. The Chicago Medical School is a nonsectarian, coeducational institution. It is chartered in the State of Illinois as a nonprofit institution. A collegiate degree is required for admission. A hospital internship is a requirement for graduation. The yearly tuition and fees are, respectively, $664, $872, $837, $649. The registration for 1952-1953 was 280; graduates 63. The last session for freshmen began Sept. 29, 1952, and for sophomores June 30, 1952, and ended June 20, 1953; the junior and senior session began Sept. 29, 1952, and ended for seniors June 27, 1953. The junior class will end Sept. 26, 1953. The next session for freshmen, juniors and seniors will begin Oct. 5, 1953, and will end June 20, 1954, Sept. 26, 1954, and June 26, 1954, respectively. The sophomore class began July 6, 1953, and will end June 25, 1954. The president is John J. Sheinin, M.D. The dean of faculty is F. J. Mullin, Ph.D.

Northwestern University Medical School, 303 East Chicago Avenue, Zone 11.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The requirement for admission is three years of collegiate work. The B.S. in medicine degree may be conferred before the end of the senior year. The total fees are $830 each year. The registration for 1952-1953 was 522; graduates 128. The last session began Oct. 1, 1952 for freshmen, sophomores and juniors and ended June 13, 1953. The senior session began June 18, 1952, and ended June 15, 1953. The next session will begin Sept. 30, 1953, for freshmen, sophomores and juniors and will end June 12, 1954. The senior session began June 17, 1953, and will end June 14, 1954. The dean is Richard H. Young, M.D.

Stritch School of Medicine of Loyola University, 706 South Wolcott Avenue, Zone 12.—Organized in 1915 by acquisition of Bennett Medical College, which had been organized in 1869. Facilities enlarged by the acquisition of Chicago College of Medicine and Surgery. Faculties in basic sciences put on full time basis and assumed name of Loyola University School of Medicine in 1917. Operated as an organic part of Loyola University. Name officially changed to Stritch School of Medicine of Loyola University on April 15, 1948. Coeducational since organization. Three years of collegiate work are required for admission. The fees are $675 a year. The registration for 1952-1953 was 334; graduates 80. The last session for freshmen, sophomores and juniors began Sept. 29, 1952, and ended June 20, 1953; the session for seniors began Sept. 8, 1952, and ended June 6, 1953. The next session will begin Sept. 28, 1953, and will end June 19, 1954, for the first two classes and will begin Sept. 8, 1953, and end June 5, 1954, for juniors, May 29, 1954 for the seniors. The dean is John F. Sheehan, M.D.

University of Chicago, The School of Medicine, 58th Street and Ellis Avenue, Zone 37.—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Division of Biological Sciences. The work of the first two years in the medical courses has been given on the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College, which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. A special function of the school is to train people for making contributions to the advancement of medical science. The requirements for admission are three years of collegiate work. The curriculim covers twelve quarters of work. The tuition fee averages $904. The registration for 1952-1953 was 281; graduates 67. Quarters begin in March, June, September and December of each year. The dean of the Division of the Biological Sciences is Lowell T. Coggeshall, M.D. All correspondence pertaining to student affairs, including admission, should be addressed to Joseph J. Ceithaml, Ph.D., dean of students.

University of Illinois College of Medicine, 1853 West Polk Street, Zone 12.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June 1912, and was restored in March 1913, when the present title was assumed. The staff of the Rush Medical College was incorporated in the University of Illinois College of Medicine in 1942 and at the same time Presbyterian Hospital, Chicago, became a teaching unit of the university. Coeducational since 1898. Three years of collegiate work are required for admission. The B.S. in medicine degree may be conferred at the end of the second year. The fees for residents of Illinois average $313 per academic year; nonresidents pay an additional fee of $300. The registration for the 1952-1953 session was 678; graduates 174. The last session began Sept. 29, 1952, and ended June 27, 1953. The next session will begin Sept. 28, 1953, and will end June 26, 1954. The acting dean is Roger A. Harvey M.D.

INDIANA

Bloomington-Indianapolis

Indiana University School of Medicine, Bloomington; 1040 West Michigan Street, Indianapolis 7.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907 by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. Three years of college work are required for admission. The work of the first two semesters is given at Bloomington; the remainder of the work at Indianapolis. Regular fee for two semesters of work is $300 for residents of Indiana and $560 for nonresidents. The registration for the 1952-1953 session was 568; graduates 134. The last session began Sept. 22, 1952, and ended June 9, 1953. The next session will begin Sept. 21, 1953, and will end June 8, 1954. The dean is John D. Van Nuys, M.D., Indianapolis.

IOWA

Iowa City

State University of Iowa College of Medicine, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. The tuition fee is $256 each year for residents of Iowa and $566 for nonresidents. The registration for 1952-1953 was 453; graduates 103. The last session began Sept. 25, 1952, and ended June 12, 1953. The next session will begin Sept. 24, 1953, and will end on June 11, 1954. The dean is Norman B. Nelson, M.D.

KANSAS

Lawrence-Kansas City

University of Kansas School of Medicine, Lawrence; 39th and Rainbow Boulevard, Kansas City.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medicochirurgical College, founded in 1897. Absorbed Kansas Medical College of Topeka in 1913. The first class graduated in 1906. At present the first year is given on the University campus at Lawrence while the remaining three years are given at the Medical Center in Kansas City, Kansas. Coeducational since 1880. The requirement for admission is three years of collegiate work, four years preferred. The fees are $475 per year; the nonresident fees are $925 per year. The registration for 1952-1953 was 450; graduates 103. The last session began June 3, 1952, and ended May 30, 1953. The next freshman class will begin Sept. 9, 1953. The sophomore class of 1953 will begin its work on Sept. 17, 1953, at Kansas City. The junior and senior classes began June 9, 1953, and will end May 29, 1954. Three-fourths of each junior and senior class is in school each quarter of the school year while one-fourth is on vacation (juniors) or preceptorship (seniors). The dean is W. Clarke Wescoe M.D., Kansas City.

KENTUCKY

Louisville

University of Louisville School of Medicine, 101 West Chestnut Street, Zone 2.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 its name was changed to the University of Louisville School of Medicine. Coeducational since organization; became non-segregational in 1951. Three years of collegiate work are the minimum requirements for admission. Tuition is $800 for residents of Kentucky and $1,200 for nonresidents, per school year. These figures include special fees excepting graduation fee of $10. The registration for 1952-1953 was 385; graduates 100. (Administratively, the school year is divided into two semesters and students are accepted for matriculation only at the beginning of the first semester. Academically, the senior and junior years are on a trimester basis, the sophomore year is divided into four unequal periods, and the freshman year into three unequal periods.) The last session began Sept. 15, 1952, and ended June 6, 1953. The next session begins on Sept. 14, 1953, and will end on June 5, 1954. The dean is J. Murray Kinsman, M.D.

LOUISIANA

New Orleans

Louisiana State University School of Medicine, 1542 Tulane Avenue, Zone 12.—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session began in October 1931 with students of first and third years. Course covers four sessions of not less than 36 weeks each. A minimum of three years' collegiate work is required for admission. Total fees, $120 each year for residents of Louisiana; additional tuition of $400 each year for nonresidents. The registration for 1952-1953 was 457; graduates 105. The last session began Sept. 2, 1952 and ended June 1, 1953. The next session will begin Aug. 31, 1953 and end May 29, 1954. The dean is William W. Frye, M.D.

Tulane University of Louisiana School of Medicine, 1430 Tulane Avenue, Zone 13.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1836 and in all subsequent years except 1863-1865, inclusive. It became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. A minimum of three years of collegiate work is required for admission. Total fees average $800 per academic year. The registration for the 1952-1953 session was 514; graduates 128. The last session began on Sept. 15, 1952, and ended on June 2, 1953. The next session will begin Sept. 14, 1953, and will end June 1, 1954. The dean is M. E. Lapham, M.D.

MARYLAND

Baltimore

Johns Hopkins University School of Medicine, 710 North Washington Street.—The nucleus of a medical faculty was constituted in 1883. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The requirement for admission is a college degree. The course extends over four years of eight and one-half months each. The fees averaged $835 per academic year. The registration for 1952-1953 was 294; graduates 76. The last session began on Sept. 29, 1952, and ended June 9, 1953. The next session will begin Sept. 28, 1953, and will end June 8, 1954. The dean is Philip Bard, Ph.D.

University of Maryland School of Medicine and College of Physicians and Surgeons, 522 W. Lombard Street, Zone 1.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine; Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Batimore was merged and the present name assumed. Coeducational since 1918. Three years of college work are required for admission. The tuition fees average $533 for residents of the state; for nonresidents $250 additional. The registration for 1952-1953 was 395; graduates 92. The last session began Sept 18, 1952, and ended June 6, 1953. The next session will begin Sept. 17, 1953, and will end June 5, 1954. The dean is H. Boyd Wylie, M.D.

MASSACHUSETTS

Boston

Boston University School of Medicine, 80 East Concord Street, Zone 18.—Organized in 1873 as a homeopathic institution. In 1874, the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Applicants are required to present a minimum of three years of premedical work. Total fees averaged $871 per year. The registration for 1952-1953 was 278; graduates 72. The last session for freshmen, sophomores, and juniors began Sept. 15, 1952, and ended May 29, 1953. The last senior class began June 9, 1952, and ended June 8, 1953. The present senior class began June 15, 1953, and will end June 7, 1954. All other classes will be enrolled Sept. 14, 1953, and the session will end May 29, 1954. The dean is James M. Faulkner, M.D.

Harvard Medical School, 25 Shattuck Street, Zone 15.—Organized in 1782. The first class graduated in 1788. At least two years of collegiate work are required for admission. The fees average $850. The registration for 1952-1953 was 529; graduates 148. The last session began Sept. 22, 1952, and ended on June 11, 1953. The next session for freshmen, sophomores and juniors will begin Sept. 28, 1953, and will end June 17, 1954. The senior class began on June 8, 1953, and will end June 17, 1954. The dean is George Packer Berry, M.D.

Tufts College Medical School, 136 Harrison Avenue, Zone 11.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. A bachelor's degree is required for admission. Enrollment is generally limited to residents of the New England States. The course covers four years Total fees for each of the four years, respectively, $863, $858, $858, $868. The registration for 1952-1953 was 438; graduates 97. The last session for freshmen, sophomores and juniors began Sept. 24, 1952; for seniors June 9, 1952, and all classes ended June 14, 1953. The present session began for the seniors on June 15, 1953, and for the other classes will begin Sept. 23, 1953, and will end June 13, 1954. The dean is Joseph M. Hayman, Jr., M.D.

MICHIGAN

Ann Arbor

University of Michigan Medical School.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed 1915. Coeducational since 1870. The entrance requirements are three years of collegiate work. The fees average $400 per academic year; nonresidents $700 a year. The registration for 1952-1953 was 683; graduates 137. The last session began Sept. 22, 1952, and ended June 13, 1953. The next session will begin Sept. 21, 1953, and will end June 12, 1954. The dean is A. C. Furstenberg, M.D.

Detroit

Wayne University College of Medicine, 1512 St. Antoine Street, Zone 26.—Organized as the Detroit College of Medicine in 1885 by consolidation of the Detroit Medical College (organized in 1868) and the Michigan College of Medicine (organized in 1879). Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1869. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit city colleges into a university system. Coeducational since 1917. Entrance requirement is three years in an accredited college or university. Until further notice, enrollment is limited to residents of the State of Michigan. The fees average $537 for the school year. The registration for 1952-1953 was 268; graduates 59. The last session began Sept. 15, 1952, and ended June 13, 1952. The next session will begin Sept. 14, 1953, and will end June 12, 1954. The dean is Gordon H. Scott, Ph.D.

MINNESOTA

Minneapolis

University of Minnesota Medical School, Zone 14.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery and reorganized in 1888 by absorption of the St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The entrance requirements are three years of university work. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Doctor of Medicine (M.D.), which is granted at the end of the course. Total fees are $352.05 per academic year for residents and $679.55 for nonresidents. The registration for 1952-1953 was 499; graduates 232. The last session began Sept. 29, 1952, and ended July 18, 1953. The next session will begin Sept. 28, 1953, and will end July 17, 1954. The school year of the first three years consists of fall and winter quarters of approximately 11 weeks and a spring quarter of approximately 16 weeks; in the senior year the spring quarter is 11 weeks in length and graduation is in June. The dean of medical sciences is Harold S. Diehl, M.D.

MISSOURI

St. Louis

St. Louis University School of Medicine, 1402 South Grand Boulevard, Zone 4.—Organized in 1901 as the Marion-Sims Beaumont Medical College by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the School of Medicine of St. Louis University in 1903. Completion of three years of college study is the minimum admission requirement, but students presenting meritorious credits in excess of minimum are accepted by preference. The fees average $896.25 per year. The registration for 1952-1953 was 499; graduates 116. The last session began Sept. 16, 1952, and ended June 1, 1953. The next session will begin Sept. 15, 1953, and will end June 1, 1954. The dean is James W. Colbert Jr., M.D.

Washington University School of Medicine, 660 S. Kingshighway, Zone 10.—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. Three years of college work are required for admission. The fees average $809. The registration for 1952-1953 was 364; graduates 95. The last session began on Sept. 15, 1952, and ended June 10, 1953. The next session will begin on Sept. 14, 1953, and will end on June 9, 1954. The dean is Robert A. Moore, M.D.

NEBRASKA

Omaha

Creighton University School of Medicine, 302 North 14th Street, Zone 2.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. Three years of collegiate work are required for admission. The tuition fees average $809 per academic year. The registration for 1952-1953 was 298; graduates 76. The last session began Sept. 16, 1952, and ended June 4, 1953. The next session will begin Sept. 14, 1953, and will end June 3, 1954. The dean is F. G. Gillick, M.D.

University of Nebraska College of Medicine, 42nd Street and Dewey Avenue, Zone 5.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. The University of Nebraska College of Medicine was established in Lincoln in 1883, and in 1902 the Omaha Medical College became a part of the University of Nebraska and has continued with the present title College of Medicine, University of Nebraska. The instruction of the first two years was given at Lincoln and of the last two years at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. Three years of college work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees average $450 per academic year; nonresidents are charged $615. The registration for 1952-1953 was 344; graduates 87. The last session for seniors began June 30, 1952, and ended June 13, 1953. The last session for freshmen, sophomores and juniors began Sept. 24, 1952, and ended June 20, 1953. The present session for seniors began July 6, 1953, and will end June 12, 1954. The next session for freshmen, sophomores and juniors will begin Sept. 23, 1953, and will end June 19, 1954. The dean is James P. Tollman, M.D.

NEW YORK

Albany

Albany Medical College, 47 New Scotland Avenue, Zone 3.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The requirement for admission is three years of college work. The fees average $825 per academic year. The registration for 1952-1953 was 215; graduates 47. The last session began on Sept. 8, 1952, for freshmen, sophomores and juniors and ended on May 29, 1953, and for the seniors the last session began on June 1, 1952, and ended on May 29, 1953. The present senior class began on June 1, 1953. The next session for the freshmen and sophomores will begin on Sept. 14, 1953, and will end on May 29, 1954. The next session for the juniors will begin on Sept. 8, 1953, and will end on May 22, 1954. The dean is Harold C. Wiggers, Ph.D.

Buffalo

University of Buffalo School of Medicine, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The minimum requirement for admission is four years of collegiate work including certain prescribed science subjects. The fees average $828. The registration for 1952-1953 was 274; graduates 59. The last session began Sept. 22, 1952, and ended June 13, 1953, for freshmen, sophomores and juniors, and began on July 7, 1952, and ended June 6, 1953, for seniors. The next session will begin Sept. 21, 1953, and end June 12, 1954, for freshmen; sophomores and juniors, and will begin Aug. 31, 1953, and end June 5, 1954, for seniors. The dean is Stockton Kimball, M.D.

New York City

Columbia University College of Physicians and Surgeons, 630 West 168th Street, Zone 32.—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. Three years of collegiate work are required for admission. Fees average $900 per academic year. The registration for 1952-1953 was 463; graduates 116. The last session began on June 9, 1952, for juniors and seniors, and ended on May 29, 1953. The last session for freshmen and sophomores began on Sept. 11, 1952, and ended May 29, 1953. The present session began on June 9, 1953, and June 1, 1953, for the juniors and seniors respectively, and will end May 29, 1954, and will begin on Sept. 10, 1953, for the freshmen and sophomores and will end May 29, 1954. The dean is Willard C. Rappleye, M.D.

Cornell University Medical College, 1300 York Avenue, Zone 21.—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. All students matriculated must be graduates of approved colleges or scientific schools or seniors *in absentia* who will receive the bachelor degree from their college on successful completion of one or more years of the medical course. The fees average $925 a year. The registration for 1952-1953 was 338; graduates 84. The last session began for senior students June 23, 1952, and ended June 10, 1953. The freshman, sophomore and junior classes began Sept. 11, 1952, and ended June 10, 1953. The present session for seniors began June 22, 1953, and will begin for the remaining three classes on Sept. 10, 1953, and all classes will end June 9, 1954. The acting dean is Dayton J. Edwards, M.D.

New York Medical College, Flower and Fifth Avenue Hospitals, 1 East 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1908; the title New York Medical College and Flower Hospital in 1936; the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. First class graduated in 1861. Coeducational since 1919. Three years of college work is the minimum requirement for admission, but a degree is preferred. The fees average $886 per academic year. The registration for 1952-1953 was 493; graduates 121. The last session began Sept. 15, 1952, and ended June 3, 1953. The next session will begin Sept. 14, 1953, for first and second year students. Third year students began June 8, 1953, and fourth year students May 25, 1953. The president is J. A. W. Hetrick, M.D. The executive dean is Ralph E. Snyder, M.D.

New York University College of Medicine, 477 First Avenue, Zone 16.—This is the undergraduate medical college of the New York University–Bellevue Medical Center which comprises also the Post-Graduate Medical School and the University Hospital. The Medical Department of New York University (then called the University of the City of New York) was organized in 1841 as the University Medical College. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. In 1947 the charter of the university and the statutes were amended establishing the New York University–Bellevue Medical Center, which includes the College of Medicine. Coeducational since 1919. Entrance requirements give preference to those who have completed not less than three full years in an approved college of arts and sciences. The fees average $900 per academic session. The registration for 1952-1953 was 529; graduates 127. The last session began Sept. 15, 1952, and ended May 23, 1953, for freshmen, sophomores and seniors, and Sept. 12, 1953, for juniors. The next session begins Sept. 14, 1953, for freshmen, sophomores and juniors, and Sept. 21, 1953, for seniors, and will end May 22, 1954, for freshmen and sophomores, Sept. 11, 1954, for juniors, and May 29, 1954, for seniors. The dean is Currier McEwen, M.D.

State University of New York College of Medicine at New York City, 350 Henry Street, Zone 2.—Originally organized in 1858 as the collegiate department of The Long Island College Hospital. The first class was graduated in 1860 and the last class in 1930. Was chartered in 1930 as Long Island College of Medicine with the first class graduated in 1931 and the last in 1949. It was merged with the State University of New York on April 5, 1950, and the first class under the University was graduated in June 1950. Coeducational. Three years of collegiate work, including specified courses, are required for admission. The fees are $715 per academic year. The registration for 1952-1953 was 590; graduates 140. The last session for seniors began Sept. 8, 1952, and ended May 29, 1953. The last session for juniors began on Sept. 15, 1952, and ended May 29, 1953. The last session for freshmen and sophomores began on Sept. 15, 1952, and ended June 6, 1953. The next session for freshmen, sophomores and juniors begins on Sept. 21, 1953, and will end on June 12, 1954. For seniors the next session will begin Sept. 14, 1953, and will end on June 5, 1954. The dean is Jean A. Curran, M.D.

Rochester

University of Rochester School of Medicine and Dentistry, 260 Crittendon Boulevard, Zone 20.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. Three years of collegiate work are required for admission. The fees are $800 per academic year. The registration for 1952-1953 was 275; graduates 64. The last session began Sept. 15, 1952, and ended June 6, 1953. The next session will begin on Sept. 21, 1953, and will end on June 12, 1954. The dean is Donald G. Anderson, M.D.

Syracuse

State University of New York at Syracuse College of Medicine, 766 Irving Avenue, Zone 10.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Assumed title Syracuse University College of Medicine in 1875, when a compulsory three year graded course was established. The College of Medicine was merged with the State University of New York on June 26, 1950, when the present title was assumed. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. Three years of collegiate work are required for admission. The fees average $800 per academic year. The registration for 1952-1953 was 278; graduates 61. The last session began Sept. 8, 1952, and ended June 6, 1953. The next session will begin Sept. 14, 1953, and end June 12, 1954. The dean is William R. Willard, M.D.

NORTH CAROLINA

Durham

Duke University School of Medicine.—Organized in 1930. The first class was admitted Oct. 1, 1930. Coeducational. The premedical requirement is three years of college work. The academic year consists of three quarters each year. There is no summer quarter between the first and second year, but in the two clinical years the subjects of the autumn, winter, and spring terms are repeated in the summer quarter. This accelerated schedule is optional, and students may take their first year, and three quarters in each of their subsequent years, and receive their certificates in four calendar years, or if they receive permission from the curriculum committee they may at the end of their second year take the clinical quarters given during the summers and receive their certificates in three and one quarter calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. Active duty with the Army, Navy or Public Health Service can replace the second year. The fees are $900 for three quarters. The registration for 1952-1953 was 315; graduates 85. During 1953 the quarters begin Jan. 5, March 30, July 6, Oct. 5, and end March 21, June 13, Sept. 19, and Dec. 19. The next first year class will be enrolled Oct. 5, 1953, and will end June 12, 1954. The dean is Wilburt C. Davison, M.D.

Winston-Salem

Bowman Gray School of Medicine of Wake Forest College, Zone 7.—Organized in 1902 at Wake Forest as a school offering only the first two years of the curriculum. In 1941 the school was moved to Winston-Salem and expanded to a complete four-year medical school under its present name. Coeducational. Three years of college work are required for admission. Clinical departments operate four quarters in the year; however, the plan of operation makes it possible for students to be out of school during one quarter of each of the clinical years for research, for study elsewhere, or for earning money to help defray expenses for their education. Tuition is $750 per school year. The registration for 1952-1953 was 206; graduates 52. The last session for the freshman class began Oct. 6, 1952; sophomores Oct. 6, 1952; juniors and seniors July 14, 1952, and ended for freshmen, sophomores, juniors, and seniors on June 13, 1953. The present junior and senior classes began July 13, 1953, and will end on June 12, 1954. The next freshmen and sophomore classes will begin Oct. 5, 1953, and will end June 12, 1954. The dean is C. C. Carpenter, M.D.

OHIO

Cincinnati

University of Cincinnati College of Medicine, Eden and Bethesda Avenues, Zone 29.—Organized in 1819 as the Medical College of Ohio. Became the Medical College of the University of Cincinnati in 1896. In 1909 the Miami Medical College (founded in 1852) was merged with the University of Cincinnati's Medical School. Coeducational since organization. Three years of collegiate work are the minimal requirements for admission but a bachelor's degree is strongly recommended. Tuition is as follows: for legal residents of Cincinnati $575 a year plus breakage fees ($125 additional for those not legal residents). The registration for 1952-1953 was 354; graduates 89. The last session for freshmen and sophomores began Sept. 22, 1952, and ended May 30, 1953. The last session for juniors and seniors began Sept. 8, 1952, and ended for juniors June 13, 1953, and for seniors May 30, 1953. The next session for juniors and seniors will begin Sept. 8, 1953, and end for juniors June 12, 1954 and for seniors May 31, 1954. The next session for freshmen and sophomores will begin Sept. 21, 1953, and will end May 31, 1954. The dean is Stanley E. Dorst, M.D.

Cleveland

Western Reserve University School of Medicine, 2109 Adelbert Road, Zone 6.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College the first class graduated in 1844. The school assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. Students are required to have three years of college work for admission; four years preferred. The fees average $800 per academic year. The registration for 1952-1953 was 324; graduates 78. The last session began Sept. 17, 1952 for freshmen and sophomores, and ended June 6, 1953. For juniors the last session began Sept. 10, 1952, and ended May 29, 1953. For seniors the last session began Aug. 25, 1952, and ended June 10, 1953. The next session for freshmen and sophomores will begin Sept. 23, 1953, and will end June 12, 1954. For juniors the session dates will be Sept. 16, 1953 to June 4, 1954, and for seniors from Aug. 31, 1953, to June 16, 1954. The dean is Joseph T. Wearn, M.D.

Columbus

Ohio State University College of Medicine, Neil and Eleventh Avenues, Zone 10.—The present College of Medicine became a part of The Ohio State University in 1914. It incorporates all the previous medical college interests in central Ohio, standing upon a foundation of six medical schools: The Medical Department of Willoughby University of Lake Erie, 1834-1846; The Willoughby Medical College of Columbus, 1846-1847; The Starling Medical College, 1847-1907; the Columbus Medical College, 1875-1892; The Ohio Medical University, 1892-1907; Starling-Ohio Medical College 1907-1914. Graduates of these colleges by action of the Board of Trustees are considered alumni of The Ohio State University. Coeducational since organization. Three years of collegiate work are required for admission. Tuition fees average $495 per academic year and $225 additional for nonresidents. The registration for 1952-1953 was 516; graduates 84. The last session began Sept. 30, 1952, and ended June 12, 1953. The next session will begin Sept. 29, 1953, and end June 11, 1954. The dean is Charles A. Doan, M.D.

OKLAHOMA

Oklahoma City

University of Oklahoma School of Medicine, 800 North East 13th Street, Zone 4.—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Oklahoma, after which a clinical department was established at Oklahoma City through consolidation with the Medical School of Epworth University. The first class graduated in 1911. Coeducational since organization. A new medical school building and a second teaching hospital became available in 1928, and since September of that year the entire four year course has been given in Oklahoma City. Prerequisites for admission are three years of college work. The fees for residents of Oklahoma are $350; nonresidents $700. The registration for 1952-1953 was 361; graduates 78. The last session began Sept. 15, 1952, and ended June 8, 1953. The next session for freshmen and sophomores will begin Sept. 14, 1953 and will end June 8, 1954. The third year class will begin on Sept. 1, 1953, and end June 8, 1954. The senior session began June 22, 1953, and will end June 8, 1954. The dean is Mark R. Everett, Ph.D.

OREGON

Portland

University of Oregon Medical School, 3181 S. W. Sam Jackson Park Road, Zone 1.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. Entrance requirement is three years of collegiate work. The total fees are $456 a year for residents of Oregon and $180 a year additional for nonresidents, plus a breakage deposit of $15 a year for the first two years. The registration for 1952-1953 was 274; graduates 71. The last session began Sept. 29, 1952, and ended June 13, 1953. The next session will begin Sept. 30, 1953, and will end June 18, 1954. The dean is D. W. E. Baird, M.D.

PENNSYLVANIA

Philadelphia

Hahnemann Medical College and Hospital of Philadelphia, 235 North 15th Street, Zone 2.—Formed by the sucessive union of several institutions. The earliest original charter was obtained in 1848. The name Hahnemann Medical College was taken by one of these institutions in 1867. The present name was assumed in 1885. The first class graduated in 1849. Coeducational since 1941. A minimum of three years of collegiate work in an approved college of arts and sciences is required for admission. Fees for 1953-1954 session are respectively for the first, second, third, and fourth year classes $847, $847, $847 and $877. The registration for 1952-1953 was 385; graduates 83. The last session began for all students Sept. 15, 1952, and ended for the first and second year classes on June 13, 1953; for the third year class June 12, 1953, and for the fourth year class on June 18, 1953. The next session for all classes will begin Sept. 14, 1953, and will end for the first and second year classes June 12, 1954, for the third year class June 11, 1954, and for the fourth year class June 17, 1954. The dean is Charles L. Brown, M.D.

Jefferson Medical College of Philadelphia, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning in 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the board of trustees. For the class entering in 1953 the minimum entrance requirements will be three years of college work. The tuition fee averages $850 a year. The registration for 1952-1953 was 662; graduates 160. The last session began for all classes on Sept. 8, 1953. Classes ended for freshmen on June 10, 1953, for sophomores on June 18, 1953, for juniors on June 4, 1953, and for seniors on May 29, 1953. Graduation was June 12, 1953. The next session will begin for all classes on September 14, 1953, and will end for freshmen on June 12, 1954, for sophomores on June 26, 1954, for juniors on June 5, 1954, and for seniors on June 18, 1954. The dean is George Allen Bennett, M.D.

Temple University School of Medicine, 3400 North Broad Street, Zone 40. Organized in 1901. The first class graduated in 1904. Coeducational since organization. Three years of collegiate work are required for admission. The fees average $800 per academic year. The registration for 1952-1953 was 508; graduates 122. The last session began Sept. 5, 1952, and ended June 13, 1953, for freshmen, sophomores, and juniors. The senior class began Aug. 18, 1952, and ended June 18, 1953. The next session will begin Sept. 5, 1953, and will end June 19, 1954. The vice president and dean is William N. Parkinson, M.D.

University of Pennsylvania School of Medicine, Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916, it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. Three years of collegiate work are required for admission. The tuition fee is $850, with a deposit of $15, a general fee including student health of $70 and a matriculation fee of $5. The registration for 1952-1953 was 511; graduates 129. The last session began Sept. 2, 1952, and ended June 6, 1953. The next session will begin Sept. 8, 1953, and will end June 12, 1954. The dean is John McK. Mitchell, M.D.

Woman's Medical College of Pennsylvania, 3300 Henry Avenue, Zone 29.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. At least three years of collegiate work are required for admission and candidates with a degree are given preference. The curriculum covers three years of 36 weeks each and one year of 40 weeks. Total fees are $860 yearly. The registration for 1952-1953 was 183; graduates 46. The last session began Aug. 4, 1952, for fourth year and Sept. 11, 1952, for all other years and ended June 13, 1953. The next session will begin Aug. 10, 1953, for the fourth year and Sept. 14, 1953 for all other classes and will end June 12, 1954. The dean is Marion Fay, Ph.D.

Pittsburgh

University of Pittsburgh School of Medicine, 3941 O'Hara Street.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. Entrance requirements are three years of collegiate work. The total fees are $700 each year. The registration for 1952-1953 was 389; graduates 99. The last session began Sept. 8, 1952, and ended June 10, 1953. The next session will begin on Sept. 14, 1953, and will end June 9, 1954. The dean is William S. McEllroy, M.D.

SOUTH CAROLINA

Charleston

Medical College of South Carolina, 16 Lucas Street, Zone 16.— Organized 1823. The first class graduated in 1825. In 1832 a medical college bearing the title Medical College of the State of South Carolina was chartered and the two schools continued as separate institutions until they merged in 1838. Name changed by Act of General Assembly in February 1952 to Medical College of South Carolina. Classes were graduated in all years except 1862 to 1865, inclusive. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. At least three years of collegiate work are required for admission. The total fees average $432 each year for residents of South Carolina and $1,532 for nonresidents of the state. The registration for 1952-1953 was 260; graduates 57. The last session began on Sept. 25, 1952, and ended June 4, 1953. The next session will begin on Sept. 24, 1953, and will end June 3, 1954. The president is Kenneth M. Lynch, M.D., and the dean is John T. Cuttino, M.D.

TENNESSEE

Memphis

University of Tennessee College of Medicine, 847 Union Avenue, Zone 3.—Organized in 1876, at Nashville as Nashville Medical College. First class graduated in 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913, Lincoln Memorial University Medical Department was merged in 1914 Coeducational since 1911. Three years of collegiate work are required for admission. The B.S. degree is conferred on students completing the science-medical curriculum of the University. The fees are $450 for residents and $675 for nonresidents. The registration for 1952-1953 was 713; graduates 155. During the next academic year the quarters begin September, January, March, and July. The vice president and dean is O. W. Hyman, Ph.D.

Nashville

Meharry Medical College, Eighteenth Avenue North and Meharry Boulevard, Zone 8 (For Negro Youth).—Organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. Three years of college work in a school of liberal arts are required for admission. Tuition and fees are: first year $631; second year $621; third year $611; fourth year $626. The curriculum covers four academic years of thirty-four weeks each. In September 1942, Meharry Medical College instituted the quarter system. The registration for 1952-1953 was 260; graduates 60. The last session began on Sept. 29, 1952, and ended on June 8, 1953. The next session begins Sept. 28, 1953, and will end on June 7, 1954. The president is Harold D. West, Ph.D., and the dean is Daniel T. Rolfe, M.D.

Vanderbilt University School of Medicine, Twenty-first Avenue South at Edgehill, Zone 5.—The school was founded in 1874. The first class graduated in 1875. Coeducational since 1925. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors *in absentia,* who will receive the bachelor degree from their college after having completed sucessfully one year of work in the school of medicine. The course covers four academic years, two of nine months each and two of ten months each. The fees average $810 per academic year. The registration for 1952-1953 was 206; graduates 51. The last session began Sept. 22, 1952, and ended June 7, 1953. The next session will begin Sept. 28, 1953, and will end June 6, 1954. The dean is John B. Youmans, M.D.

TEXAS

Dallas

Southwestern Medical School of The University of Texas, 2211 Oak Lawn.—Organized in 1943. The first class graduated March 20, 1944. Coeducational since organization. Became a branch of the University of Texas, Sept. 1, 1949. The medical school is operated on the regular program offering three terms of twelve weeks each per academic year. The tuition fees for residents average $125 per year. The nonresident fee is $375 per year. Three years of college work are required for admission. The registration for 1952-1953 was 399; graduates 98. The last session began Sept. 8, 1952, and ended June 1, 1953. The next session will begin Sept. 9, 1953 and will end June 9, 1954. The dean is George N. Aagaard, M.D.

Galveston

University of Texas School of Medicine, 900 Strand.—Organized in 1890. The first class graduated in 1892. Coeducational since organization. Three years of collegiate training are required for admission. The fees average $97 per academic year, including health fees for medical care and hospitalization. The registration for 1952-1953 was 595; graduates 138. The last session began on Sept. 16, 1952 for freshmen, Sept. 22, 1952, for sophomores, and July 7, 1952, for seniors, all classes ended June 6, 1953. The next freshman class will matriculate Sept. 15, 1953, and the sophomore and junior classes will matriculate on Sept. 21, 1953, the seniors matriculated July 6, 1953, all classes will end June 5, 1954. The director is Chauncey D. Leake, Ph.D., and D. Bailey Calvin, Ph.D. is dean of student and curricular affairs.

Houston

Baylor University College of Medicine, Texas Medical Center.—Organized in 1900 at Dallas as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. The school was moved to Houston in 1943. Coeducational since organization. The first class graduated in 1903. Entrance requirements are three years of collegiate work. The course covers four years of eight months each. The fees are respectively $775, $765, $750, $775. The registration for 1952-1953 was 365; graduates 88. The last session began Sept. 29, 1952, and ended June 8, 1953. The next session will begin Sept. 14, 1953, and will end May 31, 1954. The dean is Stanley W. Olson, M.D.

UTAH

Salt Lake City

University of Utah College of Medicine.—Organized in 1905. Coeducational since organization. Four year curriculum established, March 1943. Three years of collegiate work are required for admission. The next freshman class will be admitted in September 1953. All subsequent freshmen classes will begin in September of each year. Classes are scheduled during three academic quarters (12 weeks) each calendar year. Applications for admission (complete) must be submitted prior to October 31 preceding opening date. The fees for each quarter average $480 (resident), and $830 (non-resident). The registration for 1952-1953 was 181 and graduates 28. The next session for freshmen, sophomores and juniors will be in September 1953, and end in June 1954. The next session for seniors will begin in September 1954, and end in June 1955. The present session for seniors began in March 1953, and will end in March 1954. The dean is John Z. Bowers, M.D.

VERMONT

Burlington

University of Vermont College of Medicine, Pearl Street, College Park. —Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. Three years of college work are required for admission. For residents of Vermont the tuition fee averages $567 per session. Nonresidents are charged an additional $250 each session. A $25 fee is charged for the doctor's degree. Registration for 1952-1953 was 184; graduates 42. The last session for freshmen, sophomores and juniors began Sept. 12, 1952, and ended June 14, 1953. The last senior class began June 27, 1952 and graduated June 14, 1953. The present senior class began June 29, 1953; the next freshman, sophomore and junior classes will begin Sept. 11, 1953, and all classes will end June 13, 1954. The dean is George A. Wolf, M.D.

VIRGINIA

Charlottesville

University of Virginia School of Medicine, University Station.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. Three years of college work are required for admission. For residents of Virginia the tuition and other required fees are $465 per academic year; for nonresidents, $865. The registration for 1952-1953 was 286; graduates 70. The last session began Sept. 19, 1952, and ended June 15, 1953. The next session will begin Sept. 18, 1953, and will end June 14, 1954. The dean is Thomas H. Hunter, M.D.

Richmond

Medical College of Virginia, Twelfth and Broad Streets.—Organized in 1838 as the Medical Department of Hampden-Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. Coeducational since 1918. Classes were graduated in 1838 and in all subsequent years. Three years of collegiate work, as a minimum, are required for admission. Preference, however, is given to applicants with a baccalaureate degree. Fees average $560 per academic year. Nonresidents are charged an additional $275 each year. The registration for 1952-1953 was 366; graduates 100. The last session began Sept. 10, 1952, for second, third and fourth year classes and ended June 2, 1953. The last session for the first year class began Sept. 8, 1952, and ended June 2, 1953. The subsequent session will begin Sept. 10, 1953, for the first year class and Sept. 14, 1953, for the second, third and fourth year classes and will end June 1, 1954. The dean is John B. Truslow, M.D.

WASHINGTON

Seattle

University of Washington School of Medicine, Seattle 5.—Established by the Legislature in 1945 and organized as one of the professional schools in the Division of Health Sciences of the University of Washington in 1946. The first class graduated in 1950. Coeducational. The minimum requirement for admission is three years of collegiate work. Tuition fees are $390 each year for residents of Washington and Alaska and $585 for nonresidents of these areas. Registration for 1952-1953 was 284; graduates 72. The first three classes were limited to 50 students but with the class entering in 1949 this number was raised to 75. The last session began Sept. 22, 1952, and ended June 13, 1953. The next session will begin Sept. 21, 1953, and will end June 12, 1954. The acting dean is James W. Haviland, M.D.

WISCONSIN

Madison

University of Wisconsin Medical School, 418 N. Randall Avenue.—Organized 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. The entrance requirement is three years of collegiate work. Fees for the first, second and third years $340, for the fourth year $250 per academic year for residents. An additional fee for $320 per year is charged nonresidents. Registration for 1952-1953 was 322; graduates 76. The last session for freshman, sophomore and junior students began Sept. 22, 1952, and ended June 15, 1953. The last senior class began June 30, 1952, and ended June 19, 1953. The next freshman, sophomore and junior classes will begin Sept. 21, 1953, and will end June 14, 1954. The senior class began June 29, 1953, and will end June 18, 1954. The dean is William S. Middleton, M.D.

Milwaukee

Marquette University School of Medicine, *561 North Fifteenth Street,* Zone 3.—Organized in December 1912 by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. Three years of collegiate work are required for admission. The fees are $850 per academic year. The registration for 1952-1953 session was 390; graduates 92. The last session began Sept. 15, 1952, and ended June 5, 1953. The last senior class began June 9, 1952, and ended June 6, 1953. The next session for freshman, sophomore, and junior students will begin Sept. 14, 1953, and will end June 4, 1954. The 1953-1954 session for seniors began on June 8, 1953, and will end June 5, 1954. The dean is John S. Hirschboeck, M.D.

APPROVED MEDICAL SCHOOLS IN CANADA

ALBERTA

University of Alberta Faculty of Medicine, Edmonton.—Organized in 1913. Coeducational since organization. Has given complete medical course since 1924. Tuition for the first and second years is $425 per session, and for the third and fourth years is $450 per session. The registration for 1952-1953 was 231; graduates 52. The last session began Sept. 2, 1952, and ended April 30, 1953. The next regular session will begin Sept. 1, 1953, and end April 30, 1954. The dean is John W. Scott, M.D.

MANITOBA

University of Manitoba Faculty of Medicine, Bannatyne Avenue, Winnipeg.—Organized in 1883 as Manitoba Medical College. First class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. Matriculation requirements include three years of collegiate work in the faculty of arts and sciences of a recognized university. The course extends over four years of eight months each and a hospital internship. The fees average $438 yearly. The registration for 1952-1953 was 273; graduates 72. The last session began Sept. 8, 1952, and ended on May 15, 1953. The next session will begin on Sept. 14, 1953, and will end on May 22, 1954. The dean is Lennox G. Bell, M.D.

NOVA SCOTIA

Dalhousie University Faculty of Medicine, Morris Street, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. Requires for matriculation two years of arts. The regular medical course covers four years and a hospital internship of one year approved by the medical faculty. The fees average $415 yearly; nonresidents $250 additional fee. The last session for freshmen, sophomores and juniors began Sept. 2, 1952, and for seniors May 5, 1952; all classes ended May 12, 1953. The registration for 1952-1953 was 216; graduates 56. The next session for all classes will begin Sept. 7, 1953 and will end May 11, 1954. The dean is H. G. Grant, M.D.

ONTARIO

Queen's University Faculty of Medicine, Kingston.—Organized in 1854. First class graduated in 1855 and a class graduated each subsequent year. The course consists of six sessions of 32 teaching weeks, the sixth session being devoted entirely to clinical work in the hospitals affiliated with the University. The latter is not considered an internship. Fees for each of six years amount to $420.50. The degrees awarded are M.D., C.M. Freshman will be admitted annually. Registration for 1952-1953 was 362; graduates 57. The last session began Sept. 15, 1952 and ended May 13, 1953. The next session will begin Sept. 14, 1953, and will end May 12, 1954. The last convocation was held June 6, 1953. The dean is G. Harold Ettinger, M.D.

University of Ottawa Faculty of Medicine, Ottawa.—Organized in September, 1945. The degree of M.D. is conferred after 1 year premedical studies, 4 years medicine and 1 year of internship. The minimum academic requirements for admission to the premedical year are the Ontario grade 13 honour matriculation, or equivalent certificates. Students who have obtained their bachelor degree in arts or in science and who have completed the required courses in biology, chemistry, and physics may be admitted to the first year of medicine. The registration for 1952-1953 in the medical and premedical years was 251. The next session for the premedical year will begin on Sept. 10, 1953, and for first, second, third, and fourth medical years, on Sept. 8, 1953. Internship is from May 1 to May 1. The session for the premedical year will end in May, 1954, for first, second, and third medical years in June, 1954, and the fourth medical year in April, 1954. Students graduate in the first week of June. The dean is A. L. Richard, M.D.

University of Western Ontario Faculty of Medicine, 346 South Street, London.—Organized in 1881 as the Western University Faculty of Medicine. First class graduated in 1883 and a class graduated each subsequent year. Present title in 1923. The Faculty of Medicine has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The normal course of study covers two honor college years of nine months each and four years of nine months each in the Faculty of Medicine. The total fees to residents of Canada for the last four years are $550 a year. The registration for 1952-1953 was 238; graduates 61. The last session began Sept. 8, 1952, and ended May 20, 1953. The next session begins Sept. 14, 1953, and ends May 26, 1954. The dean is J. B. Collip, M.D.

University of Toronto Faculty of Medicine, Toronto 5.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The degree of M.D. is conferred after 4 years in the study of medicine. Admission to the medical course is gained following honour matriculation and after two years in the study of premedical requisites in the University of Toronto. A certain number are admitted each year to the first medical year who hold arts degrees from recognized universities and who have covered the necessary work in the humanities and sciences. The B.Sc. (Med.) degree may be conferred for special work or investigation as a graduate degree, or under certain circumstances for an extra year's work as an undergraduate. The registration for 1952-1953 in the medical and premedical years was 883; graduates 162. The next session for first and second premedical years will begin on Sept. 23, 1953 and for first, second, third and fourth medical years on Sept. 21, 1953. The session for premedical years will end on May 1; 1954, and for medical years on May 15, 1954. Students will graduate annually in June. The dean is J. A. MacFarlane, M.B.

QUEBEC

McGill University Faculty of Medicine, 3640 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1917. Three years of collegiate work are required for admission. The total fees for each of the four medical years are $593. The registration for 1952-1953 was 442; graduates 115. The last session began Sept. 3, 1952, and ended May 30, 1953, for the first three classes and May 2, 1953, for the senior class. The next session will begin Sept. 9, 1953, and will end June 5, 1954, for the first three classes and May 1, 1954, for the seniors. The dean is G. Lyman Duff, M.D.

University of Montreal Faculty of Medicine, 2900 Mount Royal Boulevard, Montreal.—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, was merged with the Faculty of Medicine of Laval University at Montreal (organized in 1878). Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The requirements for admission are: B.A. degree or its equivalent, with a supplementary year in the Faculty of Pure Science or an entrance examination on the premedical subjects. An internship is required for graduation. The fees are $390 yearly for residents, and $465 yearly for nonresidents. The registration for 1952-1953 was 414; graduates 89. The last session began Sept. 9, 1952, and ended May 22, 1953. The next session will begin Sept. 10, 1953, and will end May 23, 1954. The dean is Wilbrod Bonin, M.D.

Laval University Faculty of Medicine, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The premedical requirement is a B.A. degree. The medical course is six years in length, lincluding a one year internship in affiliated teaching hospitals. The first year (premedical) may be avoided by a special examination The fees for each of the medical years average $400 for residents of Canada. Nonresidents are charged an extra fee of $200 each year. The registration for 1952-1953 was 603; graduates 108. The last session began Sept. 15, 1952, and ended June 1, 1953. The next session will begin Sept. 14, 1953, and will end June 5, 1954. The dean is Charles Vézina, M.D.

APPROVED SCHOOLS OF THE BASIC MEDICAL SCIENCES IN THE UNITED STATES

MISSISSIPPI

University

University of Mississippi School of Medicine.—Organized in 1903. Coeducational since organization. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. Entrance requirement is three years of collegiate work. Fees average $410.50 annually. There is a nonresident additional fee of $200. The school operates on an accelerated program by accepting two freshman classes each session. Registration for 1952-1953 was 109 The last session for freshmen began July 14, 1952, and ended May 2, 1953. An additional freshman class was admitted Jan. 5, 1953, and will end Oct. 10, 1953. The sophomore session began May 26, 1952, and ended Jan. 31, 1953. An additional sophomore session began Oct. 27, 1952, and ended July 3, 1953. The dean is David S. Pankratz, M.D.

MISSOURI

Columbia

University of Missouri School of Medicine.—Organized at St. Louis in 1845; was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The entrance requirement is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are $249, for the second year $235. The registration for 1952-1953 was 83. The last session began Sept. 11, 1952, and ended June 7, 1953. The next session will begin Sept. 15, 1953, and will end June 12, 1954. The dean is Roscoe L. Pullen, M.D.

NEW HAMPSHIRE

Hanover

Dartmouth Medical School.—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the Trustees of Dartmouth College. Courses of the third and fourth years were discontinued in 1914. Three years of college work and candidacy for the bachelor's degree are required for admission. Candidates for the A.B. degree in Dartmouth College may substitute the work or the first year in medicine for that of the senior year. The tuition is $800 for each year. The registration for 1952-1953 was 48. The last session began on Sept. 21, 1952, and ended June 14, 1953. The next session will begin Sept. 20, 1953, and will end June 13, 1954. The dean is Rolf C. Syvertsen, M.D.

NORTH CAROLINA

Chapel Hill

University of North Carolina School of Medicine.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh. The first class was graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of college work are normally required for admission. The tuition is $600 per year for residents; for nonresidents an additional $600 per year. The registration for 1952-1953 was 167. The North Carolina legislature in 1947 appropriated funds for the expansion of the school to the full four years. The first senior class will graduate June 7, 1954. The last regular session began Sept. 22, 1952, and ended June 8, 1953. The next session will begin Sept. 18, 1953, and will end June 7, 1954. The dean is W. Reece Berryhill, M.D.

NORTH DAKOTA

Grand Forks

University of North Dakota School of Medicine.—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years work in a college of liberal arts are required for admission. The B.S. degree in combined arts-medical course is conferred at the end of the second year. The fees are $126.50 each year for resident students and $206.50 for nonresidents. The registration for 1952-1953 was 72. The last session began Sept. 15, 1952, and ended June 9, 1953. The next session will begin Sept. 18, 1953, and will end June 5, 1954. The dean is Theo. H. Harwood, M.D.

SOUTH DAKOTA

Vermillion

University of South Dakota School of Medical Sciences.—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Three years work in a college of liberal arts are required for admission Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to an A.B. degree: The B.S. degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A.B. degree. The tuition is $270 for the first year residents and $360 for second year residents; $480 for first year nonresidents, and $570 for second year nonresidents. Registration for 1952-1953 was 63. The last session began Sept. 1, 1952, and ended June 4, 1953. The next session for first and second year students will commence Sept. 1, 1953, and will end June 5, 1954, for first year students and will end June 30, 1954, for second year students. Following the didactic work in the second year, the sophomores spend a three week period of clerkship at the three Sioux Falls hospitals. After this they are assigned to a physician in general practice in the state for a three-week preceptorship program. The dean is W. L. Hard, Ph.D.

WEST VIRGINIA

Morgantown

West Virginia University School of Medicine.—Organized in 1912. Gives the first two years of the medical course, but agreement has been made for the transfer of 25 students each year to the Medical College of Virginia. Coeducational since organization. Entrance requirements are three years of collegiate work. The B.S. degree is conferred at the end of the second year. Fees for residents of the state are, respectively, $258 and $268; nonresidents, $442 additional each year. The registration for 1952-1953 was 60. The last session began Sept. 15, 1952, and ended June 1, 1953. The next session will begin Sept. 14, 1953, and will end May 31, 1954. The dean is Edward J. Van Liere, M.D.

APPROVED SCHOOL OF THE BASIC MEDICAL SCIENCES IN CANADA

SASKATCHEWAN

University of Saskatchewan School of Medical Sciences, Saskatoon.—Organized in 1926. Coeducational. Offers the first two years of the medical course. Two years of university premedical work is required for admission. The B.A. degree is conferred at the end of the second year. The fees are $380. The registration for 1952-1953 was 61. The last session for freshmen began Sept. 24, 1952, and ended June 17, 1953. The next session will begin Sept. 23, 1953, and will end June 9, 1954. The dean is J. Wendell Macleod, M.D.

FIFTY-THIRD ANNUAL REPORT ON MEDICAL EDUCATION

In this issue of THE JOURNAL is the 53rd Annual Report on Medical Education in the United States and Canada prepared by the Council on Medical Education and Hospitals as a public service. Among the most important and interesting events of the past year are those that reflect the critical reevaluation to which the whole of medical education has been subjected since the end of the war. A considerable number of innovations made last year by the schools and plans for revision of programs are listed in this report. The one certain to attract the most attention is the experimental program of undergraduate medical education inaugurated at Western Reserve University, where the traditional departmental approach to teaching has been abandoned and the entire curriculum organized on the basis of multidisciplined, correlative teaching. A brief outline of this experimental program is contained in this report, and a fuller discussion of its present development will be found in the Proceedings of the Annual Congress on Medical Education and Licensure.

The wide and intense interest in improving medical education was also reflected in the First World Conference on Medical Education, which was held in London, England, in August. Men from all parts of the world met at this conference to pool their experiences and to discuss major educational problems of importance in medicine.

The most urgent problem, one which has faced the medical schools ever since the end of World War II, is the financial one. Although large sums have been expended for the development of facilities and for seven consecutive years budgets of the schools have steadily increased, there remains an urgent need for additional funds. The increases in available funds have not been distributed uniformly among the schools, and many schools are in need of capital funds for the improvement and expansion of their facilities, especially those for the basic medical sciences. Increases in operating budgets have been offset in some measure by increases in costs and in the educational and service responsibilities of the schools.

In an effort to estimate the financial needs of the schools for operating funds, the Council on Medical Education and Hospitals and the Association of American Medical Colleges have instituted an intensive study of the problem. It is hoped that the results of this study will be available late this year or early in 1954. Recent information on the cost of attending medical school, as might be expected, shows there has been a definite increase in cost since similar data were collected three years ago. The average cost of attending medical school this year was $2,000 as compared with $1,800 three years ago.

This year for the first time, the schools were requested to furnish data on the total amounts of scholarship and loan funds that are available to their undergraduate medical students. There was great variation in the sums available for these purposes. While some schools are fortunate in having access to rather large funds, the average amount available for scholarships was only $12,014 and the average for loan funds was $41,201. The smallest scholarship fund reported was $300, and the smallest loan fund was $500. It is apparent that a certain number of schools can offer little assistance to students needing financial help. In fact the small amounts of funds make it appear that in some instances no vigorous effort has been made to obtain money for these purposes.

The 1952 freshman class and the expected freshman class for 1953 are both slightly smaller than the record class of 1951. This leveling off after a long period of marked and progressive growth in the size of entering classes is interpreted as a readjustment by the schools to near capacity operation. When expansion programs now under way are completed and when new medical schools now in the final stages of development are in full operation, there will be further increases in the size of the entering class. Total student enrollments will continue to advance, since the entering class, although somewhat smaller than that of the previous year, was still larger than the graduating senior class.

Special attention is directed to the fact that, for the second year, the number of graduate students and physicians enrolled in courses leading to graduate degrees in the basic medical sciences has decreased. There has been a total decrease, for the two year period, of 27%. The decline in the ranks of potential teachers in these vital areas, where teachers are already in short supply, is a matter of grave concern, for, unless the supply of basic science teachers can be increased, it will not be possible to continue to expand facilities for training physicians and the quality of existing programs is certain to suffer. This situation helps to highlight the financial problem of the medical schools. For, while it is conceded that salaries in basic science departments are in many instances higher than salaries of similar ranks in other university departments, they still are not high enough to compete successfully with the opportunities available in clinical medicine, in industry, and in certain other professional fields.

It is obviously impossible to predict what demands national defense will make on medical education in the near future. The present truce in Korea may result in some reduction or delay in calling up of physicians under the amended "Doctor-Draft" law of 1953. However, the long-term needs of national defense are such that, for the forseeable future, virtually all medical students deferred from military service for the purpose of completing their medical education should expect, on completion of their internships, to serve with the armed forces.

FINAL REPORT OF SURVEY OF MEDICAL EDUCATION

"Medical Education in the United States at Mid-Century," the final report of the Survey of Medical Education, is now available in book form.[1] This volume will be of the greatest interest not only to those directly involved in medical education but also to practicing physicians who are frequently called on to interpret medical education and the problems of medical schools to the citizens of their communities.

The survey was organized in 1947 by the Council on Medical Education and Hospitals and the Association of American Medical Colleges. Its purpose was to evaluate critically the present programs of the medical schools, to determine the degree of success with which they are meeting their social and educational responsibilities, and to assess, in their broad aspects, the future responsibilities of medical education.

The attainment of these objectives has been a tremendous task, requiring detailed and comprehensive study of all aspects of the activities of medical schools. Data on which the report is based were obtained from an intensive first-hand study of 41 representative schools by the survey staff, from questionnaires sent to all of the medical schools in the United States, and from information accumulated over a period of many years by the Council on Medical Education and Hospitals and the Association of American Medical Colleges.

The report covers the function of the medical schools in education, research and service, finances, administrative organization policies and practices, curriculum and teaching methods, and advanced education, including internship and residency training, graduate training in the basic medical sciences, and postgraduate training. These programs are critically analyzed and recommendations made for their improvement.

Among the significant contributions of the report is its portrayal of the multiplicity and complexity of the responsibilities that are borne by a modern medical school. The rapid evolution of modern science and its application to medicine, together with the sweeping changes that have occurred in recent decades in the social milieu, have profoundly affected the teaching of medical science and its applications. These changes have created, for medical education, unprecedented problems for which there is no easy solution. The rapid expansion of research programs, particularly in the past 15 years, and the service obligations in which medical schools have become involved have placed strains on their finances that have impaired and even jeopardized the basic undergraduate educational programs. The report makes evident the need for clear definition and delineation of the scope of activities that should be undertaken by the medical schools and indicates methods by which the schools may improve their situation.

The enormous expansion in scientific knowledge, much of it revolutionary in character, and the attempt to incorporate large amounts of this material in the traditional pattern of medical education has distorted and overburdened the curriculum. There is a great need for new thinking in this area and for extensive revision of the curriculum. It is also apparent that, if the schools are to be successful in producing physicians competent to apply modern medical science and to advance it, premedical training must be improved and better methods for selection of students to be admitted to medical school must be developed.

The Flexner Report on medical education in the United States, published in 1910, had a revolutionary impact on American medical education. This report, together with the ferment that it stimulated, resulted in the elimination of the proprietary medical schools and the establishment of medical schools on a true university basis. Much critical thinking and hard work have been done by medical faculties in the ensuing years in the development of their programs. Despite the serious problems that now face the schools, the situation is in no way comparable to that of half a century ago, and it can hardly be expected that the present report will result in changes as great as those following the Flexner Report. Nevertheless, the problems now facing the schools call for extensive modification of the programs of the medical schools, and the schools will be assisted tremendously in this undertaking by the critical analyses and the recommendations offered in the report of the survey.

PRIVATE PATIENTS IN MEDICAL TEACHING

A major problem in medical education today is the extent to which private patients can be utilized in the education of medical students, interns, and residents and the best methods of developing teaching programs centered entirely or largely around private patients. A related problem of tremendous interest and importance to many hospitals with few or no service beds is how such hospitals can develop teaching programs that will enable them to compete successfully for competent interns and residents with hospitals maintaining large public wards.

A stimulating analysis and discussion of this important problem is presented in the article "Private Beds in Medical Teaching" by S. Howard Armstrong Jr., which appears in this issue of THE JOURNAL. Armstrong maintains that, provided certain criteria are met, teaching can be carried out successfully with private patients at all levels except possibly with that of the senior residency. These criteria may be summarized as follows: The patients must present the range of serious disease that physicians will encounter later in their careers. Opportunity must be available for students and house staff to follow the course of patients after discharge from the hospital. The members of the staff must be devoted to teaching and willing to make the sacrifice of time and effort that good teaching requires. The attending physicians must be sufficiently secure in their relationships to their patients to share responsibility with junior colleagues. Finally, the attending staff must be sensitive to the difference between mere training and true education.

It is pointed out that the most difficult problems in utilizing private patients involve not the patient but the relationship of physicians to each other. The nature of these problems are analyzed at length in the paper, and examples of their successful solution are cited.

This discussion is notable for its realistic understanding of the problems facing student, intern, resident, full-time teacher, the practicing physician and the patient in the organization of an effective educational program centered around private patients. The prerogatives and interests of the practicing physician in his relationship to his private patients are respected at the same time that his responsibilities to the students, interns, and residents assigned to him are emphasized. The desirability of giving the intern and resident increasing responsibility is balanced against their capacity to assume such responsibility and the welfare and rights of the patient.

---

[1] Deitrick, J. E., and Berson, R. C.: Medical Schools in the United States at Mid-Century, New York, McGraw-Hill Book Company, 1953.

No ready-made answer to the whole problem of how private patients may best be utilized is advanced, and the author frankly raises questions to which he does not have the answers. The report was prepared for the practicing physician who wants background information on modern processes and standards of clinical education to strengthen teaching in his own hospital. A careful study of this report by hospital staffs should aid them significantly in an evaluation of the effectiveness and attractiveness of their own teaching programs.

FILTRABLE AGENT CAUSING MOUSE SALIVARY GLAND CARCINOMA

Gross[1] of the Veterans Administration Hospital, Bronx, New York, has recently demonstrated that leukemia developing "spontaneously" in mice of the Ak inbred line is actually caused by a filtrable agent, transmitted directly through the embryo.[2] The presence of the agent in extracts prepared from leukemic organs of Ak mice was demonstrated by a bioassay consisting of the injection of such extracts into mice of the C3H line, known to have been essentially free from spontaneous leukemia. The use of newborn animals for inoculation of the extracts proved to be essential in this work, since it soon became evident that the susceptibility of the mouse to experimental infection with the leukemic agent is for all practical purposes limited to the first few hours after birth. After successful inoculation with the leukemic extracts, the mice that had received the injections remained, at first, in good health, but "spontaneous" leukemia developed after they reached middle age, i. e., after a latency of at least several months, and in some instances after an interval exceeding a year or a year and a half.

When, in more recent experiments, Gross[3] passed the Ak leukemic extracts through porcelain filter candles (Selas), having a very fine porosity (O3), and injected the resulting filtrate into newborn C3H mice, the results were surprising: while 9 of the 84 inoculated animals died from typical leukemia, in 15 others bilateral salivary gland carcinomas developed, unexpectedly, instead of leukemia, arising in multiple foci in the parotid glands. In some of these mice metastatic carcinomas developed in the axillary and inguinal pits. There was, however, in these 15 animals, no general involvement of the lymph nodes, no infiltration of liver, spleen, or other organs, and no pathological changes in either the bone marrow or the peripheral blood picture. The average age of mice in which the salivary gland carcinomas developed was 3.3 months, far below that at which spontaneous leukemia usually develops.

Although salivary gland tumors have been observed, on very rare occasions, to develop spontaneously in old mice of certain inbred strains, such as strain C or A, they have not been recorded in either mice of the C3H line (serving as test animals for inoculations), or those of the Ak line; yet mice of the Ak line served as donors of the leukemic organs for which extracts had been prepared for inoculation of the C3H mice. It is conceivable, therefore, that mice of the Ak line carry two different oncogenic agents. One of these agents would be potentially capable of causing the development of leukemia and the other that of salivary gland carcinomas. Since salivary gland tumors do not develop spontaneously in mice of the Ak line, whereas leukemia is common in these animals, it would follow either that mice of the Ak line are not susceptible to the pathogenic action of the salivary tumor agent or that an interference phenomenon may be responsible for the apparent suppression of the pathogenic potentiality of the salivary gland tumor agent by the simultaneous presence of the leukemic agent. In any event, both agents could be experimentally extracted from leukemic organs of Ak mice. They could be separated by ultracentrifugation at 144,000 × g, the carcinoma agent remaining mainly in the supernate, or by passing the extracts through filter candles of very fine porosity, apparently retaining at least some of the leukemic agent, but passing freely the smaller salivary gland tumor agent. It also appears that the salivary gland tumor agent is slightly more resistant to high temperature than the leukemic agent, heating to 68 C and 65 C for 30 minutes, respectively, being required for inactivation. Both agents were found in normal, healthy Ak embryos, suggesting thereby that both are being transmitted, in mice of the Ak line, from one generation to another.

The implications of these findings for human pathology could be of considerable interest. Should leukemia be caused by a transmissible agent not only in chickens and mice but also in man, the possibility would have to be considered that in man also the leukemic agent may be accompanied by another oncogenic agent, potentially capable of causing some forms of sarcoma or carcinoma. As in mice, in man also such oncogenic agents could be transmitted, in their inactive form, coupled together and not causing any symptoms, from one generation to another. An interference phenomenon might be responsible for the apparent latency of either, or both, agents in most of the carrier-hosts. Occasionally, however, prompted perhaps by an accidental segregation of such agents, an activation of either agent may now and then occur, resulting in the development of leukemia in some, and carcinoma or sarcoma in other members of the same family tree. This hypothesis[4] may explain clinical observations suggesting that in families of patients with leukemia, malignant tumors, such as carcinoma or sarcoma, are commoner than in the average population.

In any event, the discovery of another malignant tumor caused by a filtrable, thermolabile, and transmissible agent adds one more tumor to the impressively growing list of virus-caused neoplasms.

ORGANIZATION SECTION

STATEMENT BEFORE HOUSE COMMITTEE ON RETIREMENT FUNDS FOR SELF-EMPLOYED PERSONS

Gentlemen: I am Dr. Edward J. McCormick of Toledo, Ohio, where I am engaged in the active practice of medicine. I am President and a member of the Board of Trustees of the American Medical Association. I am appearing here today as a representative of that Association relative to measures currently pending before your Committee which are designed to provide retirement funds for self-employed persons and others not covered by existing pension plans. With me is Frank G. Dickinson, Ph.D., Director of the Bureau of Medical Economic Research of the Association. At the conclusion of my brief statement I should like to have Dr. Dickinson discuss the technical details of the proposals under consideration.

At the outset I would like to state that the American Medical Association has, for a number of years, endorsed the principle of legislation of this type. In the early part of 1948 there came to the attention of the Board of Trustees a movement then under way to promote the enactment of federal legislation under which self-employed persons, including physicians, could provide for their own retirement benefits through the deduction of amounts annually from their taxable income to finance retirement plans. The Board approved this movement with the stipulation that there would be a reasonable limitation on retirement benefits for which provision could be made. This action was commended by our House of Delegates in June, 1948.

In June, 1951, at the annual session of the American Medical Association three resolutions were adopted by the House of Delegates re-emphasizing the Association's endorsement of this principle.

On May 13, 1952, representatives of the Association appeared before this Committee in general support of H. R. 4371 and H. R. 4373, 82d Congress (Dickinson, F. G.: An Analysis of the Keogh-Reed Bill to Encourage Pensions for the Self-Employed, Bulletin 89, Bureau of Medical Economic Research, American Medical Association, 1952). However, at that time various amendments were suggested. The bills which are now pending before your Committee include all of the amendments recommended by the Association at that time.

In June and again in December, 1952, the House of Delegates reiterated its endorsement of these proposals and recommended that each member of the Association give careful study and active support to their passage.

It is the belief of the American Medical Association that physicians, dentists, lawyers, architects, farmers, store owners and the many others who comprise the nation's self-employed have long been neglected in federal tax legislation relating to pensions. The purpose of these bills is to eliminate the discrimination and inequities existing under present tax laws. By extending the tax deferment privilege to the country's 11,000,000 self-employed and also to millions of employees who are not covered by pension plans, this legislation will give them increased incentive to save for their old age during their best earning years.

This legislation will be of particular benefit to physicians who go through a long and costly period of training and whose earnings are bunched into a comparatively short period of years when they are subject to high income tax rates.

The need for such relief was demonstrated recently in the case of Kintner vs. U. S. (107 Fed. Supp. 976) in which the status of physicians in group practice under Section 165(a) of the Internal Revenue Code was in question. Although pointing up the need for the inclusion of physicians, among others, under Section 165(a), the case will not, even if Dr. Kintner's position is upheld, be of significant assistance since less than 5% of private practitioners are involved.

Under the program proposed by the pending bills the amount of each person's pension would be determined by his contributions without one cent being added by the government. In addition, the program would not force a person into idle retirement in order to draw upon his pension fund. Most important, it presents an opportunity for all who can pay for their own retirement to do so.

That, very briefly, indicates the general viewpoint of the American Medical Association toward this legislation. We have collaborated very closely in the development of this legislation with representatives of the American Bar Association, the Association of the Bar of the City of New York and with national organizations of self-employed tax payers who would be afforded some measure of equity taxwise by the enactment of the pending measures. I urge, therefore, that your Committee give favorable consideration to this legislation.

FROM THE SECRETARY'S LETTER

The following item appears in the July 29 issue of the *Secretary's Letter, which is sent by A. M. A. Secretary George* F. Lull to officers of the American Medical Association and to county and state medical associations:

Speaks His Mind on A. M. A. Policy. In a recent issue of the Utah Medical Bulletin, Dr. K. B. Castleton authored a "President's Page" article on the June meeting of the A. M. A. in New York. He concluded his piece with some pertinent statements regarding A. M. A. policies. He said:

"Many doctors are very critical of the A. M. A. leadership and policies. Many feel that the A. M. A. does not adequately represent the private physician, is undemocratic, ultraconservative, and 'asleep at the switch.'

"After attending the last two House of Delegates meetings, I am convinced that the A. M. A. is conscientiously attempting to do the best job possible, not only for the doctors but what is of much greater importance for the people of this country as a whole so far as medical care is concerned.

"I believe it is a democratic organization, its policies being determined by the House of Delegates, the members of whom are elected by us. I am convinced that these men are honest, hard working, unselfish, intelligent men who are devoting an enormous amount of time, thought and energy to our affairs, and we all owe them a great debt of gratitude. Their work I am sure is not appreciated as it should be. If any of you have any doubts along this line I would suggest that you make it a point to visit the House of Delegates meetings during the next few conventions and watch it work. Go along with George Fister and see how much time and how much hard work is involved.

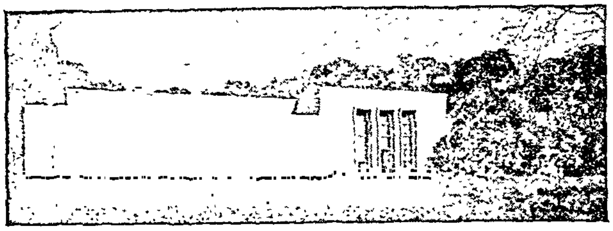
"If any of you do not like the way the A. M. A. is run, you should make your ideas known at your county medical meetings, introducing resolutions which may be carried to the House of Delegates of the Utah State Medical Association, thence to our delegate and thence to the A. M. A. Every member of our organization has the right and privilege to express his own feeling and to inaugurate changes which will be carried through if there are enough members of the society who believe as he does."

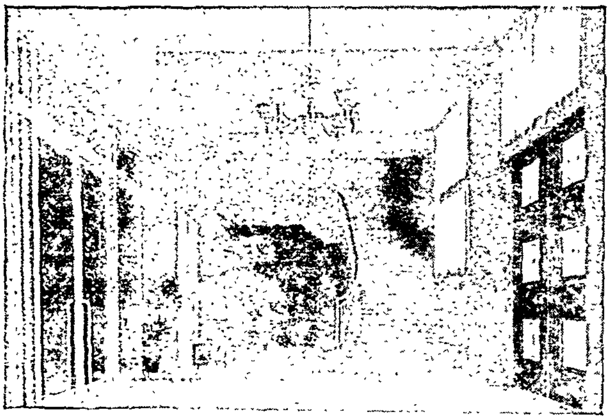
CONFERENCE OF SCHOOL HEALTH LEADERS

The American Medical Association's fourth national Conference on Physicians and Schools, sponsored biannually by the Bureau of Health Education, will be held Sept. 30 and Oct. 1-2 at the Moraine Hotel, Highland Park, Ill. More than 200 representatives of state health departments, state education departments, and state medical societies have been invited to participate in the discussions. Following the theme of "Health Services for *School Children,*" those attending the conference will break up into a dozen different groups to discuss specific problems and develop suggested policies and practices. In addition, medical, public health, and educational leaders from 18 large cities will discuss big city problems in school health.

TEXAS MEMORIAL LIBRARY

The Texas Medical Association has placed its offices with its Memorial Library under one single roof. Dedicated in September, 1952, the large and attractive Indiana-limestone structure, affording 32,676 square feet of floor space, houses the entire headquarters for the Texas association. The main library and its supporting units occupy the entire lower floor and includes a foyer, spacious reading room, rare-book room, the auditorium (named the Sam Thompson Room in honor of Dr. and Mrs. Sam E. Thompson of Kerrville, who have contributed $50,000 for the building and operation of the library), film editing and cutting room, coffee room, and large reference room. The Sam Thompson Room has a complete and modern kitchen for serving the many meetings and film showings held there annually. On the second floor are the executive, business, journal and physician-placement offices, as well as those of public relations, state advisory committee, and the auxiliary. Augmenting these are the mailing and reproduction rooms, central files, and switchboard.





The Memorial Library provides eight hours of service daily to the many association members it serves free of charge. The library also maintains a film loan service, and about 1,000 requests are processed annually. It consists of 150 films for professional persons and 50 for lay audiences.

Factbook on Medical Education, based on the 52nd Annual Report on Medical Education in the United States, prepared by the Council on Medical Education and Hospitals.

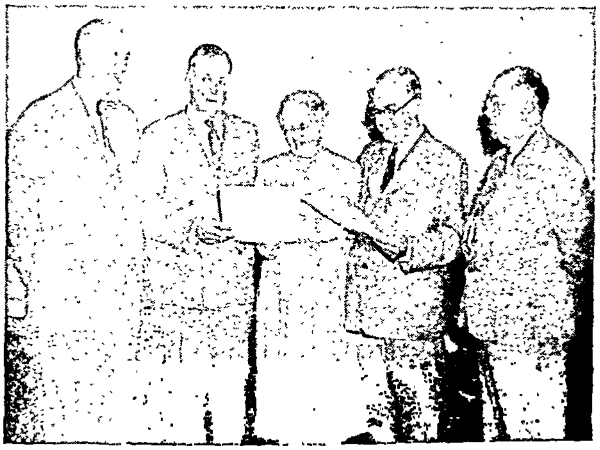
ADVANCE REGISTRATION FOR CLINICAL MEETING

The Membership-Subscription Department will mail advance IBM registration cards (about Nov. 1, 1953) for the St. Louis Clinical Meeting. These cards will be sent to all members in good standing for the year 1953, in the following states: Alabama, Arkansas, Illinois, Indiana, Iowa, Kansas, Kentucky, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Ohio, Oklahoma, Tennessee, Texas, and Wisconsin.

All paid A. M. A. members in states not listed above will be sent advance registration cards on request. All requests should be addressed to the Membership-Subscription Department, Advance Registration Section, 535 N. Dearborn Street, Chicago 10, Ill. For a convenient and speedy registration, physicians are requested to present these advance registration cards at the registration booth, Keil Auditorium, St. Louis, on the following registration days and hours: Nov. 30, 10 a. m. to 4 p. m., Dec. 1-4, 8:30 a. m. to 5:30 p. m.

SCROLLS FOR COFOUNDERS OF RURAL HEALTH COUNCIL

Scrolls of appreciation from their friends and associates in rural health work are presented to Mrs. Charles W. Sewell of Otterbein, Ind., and Dr. F. S. Crockett of Lafayette, Ind., the two cofounders of the Council on Rural Health of the American Medical Association. The scrolls, signed by all members of the Council and of its Advisory Committee, were presented during the recent Summer Agricultural Conference at Purdue University. Taking part in the program (left to right) were Dr. Paul D. Crimm of Evansville, president of the Indiana State Medical Association; Dr. George F. Lull of Chicago, Secretary and General Manager of the American Medical Association; Mrs. Sewell; Dr. Crockett; and L. E. Hoffman, associate director of agricultural extension at Purdue and a member of the Indiana Rural Health Committee.



PUBLIC RELATIONS IN THE DOCTOR'S OFFICE

Several medical societies have purchased quantities of the A. M. A. office plaque, "To All My Patients," for distribution to their members. The Dade County Medical Association in Miami ordered 1,000 plaques to be placed in every doctor's office in the city. The Oklahoma State Medical Association requested a supply of plaques for presentation to all of its incoming members. Designed by the American Medical Association, this plaque invites patients to feel free to ask questions regarding the doctor's services or fees. Individual physicians may purchase plaques from the Order Department, 535 North Dearborn Street, Chicago 10, Ill. The price is one dollar per copy.

MEDICAL NEWS

ALABAMA

Dr. Hannon Honored.—At its conference in Ft. Morgan, the Alabama Crippled Children's Rehabilitation Service honored Dr. William C. Hannon, Mobile, for "his outstanding work with crippled children of this area during the past 25 years." It was pointed out that most of Dr. Hannon's work was "where his only reward was the satisfaction of knowing he was helping some unfortunate person to lead an easier and happier life." One of his patients, a 13-year-old boy, was a guest of honor. A television set was presented to Dr. Hannon.

CALIFORNIA

Stanford Medical School to Move to Palo Alto.—The board of trustees of Stanford University, Stanford University-San Francisco, has announced that the university's new medical school will be constructed on the Palo Alto campus within three to five years. According to the president, J. E. Wallace Sterling, the decision to move the medical school is based on the conviction that the future of medical education is dependent on the course of medical science, which has become increasingly dependent on the basic physical sciences and the social sciences. "This key relationship of medical education and science to other scientific fields," he stated, "can best be strengthened and advanced by bringing the medical school into the closest possible physical and intellectual relationship to the whole university." It is anticipated that affiliated facilities, such as the Stanford University Hospitals, Stanford School of Nursing, Lane Medical Library, and Stanford clinics, will be brought to the Palo Alto campus but that the university will continue its postgraduate programs at San Francisco Hospital.

COLORADO

Dr. Marcial to Study Abroad.—Dr. Victor A. Marcial, who is affiliated with Penrose Cancer Hospital, Colorado Springs, left recently to attend the International Congress of Radiobiology in Copenhagen, Denmark, before visiting the Radiumhemmet in Stockholm, Sweden. He plans to study at the Royal Cancer Hospital and the Mayerstein Institute of Radiotherapy in London, the Holt Radium Institute of Manchester, England, and the Radium Institute of the University of Paris (Sorbonne) in France. Dr. Marcial will attend the International Cancer Congress in São Paulo, Brazil, before returning to the United States in 1954. The American Cancer Society recently chose Dr. Marcial as the first recipient of a fellowship to continue work in therapeutic radiology.

ILLINOIS

Personal.—Dr. Guy F. Turner was guest of honor at the annual homecoming in Long Point, where he has practiced medicine for 50 years. Dr. Turner has also served Long Point as postmaster, head of the village board, and president of the high school board of education.

Scientific Speakers Wanted.—The scientific service committee of the Illinois State Medical Society is revising, for the first time since 1947, its list of speakers available to county medical societies. Physicians wishing to be included are urged to send in their names together with a list of the subjects for which they would be available. If the physician does not have a teaching position connected with a medical school, his hospital staff affiliation should be included. Mention should also be made of the type of slides used in talks and titles of movies if available. Submit data to Dr. Louis R. Limarzi, chairman, Scientific Service Committee, Illinois State Medical Society, Room 801, 185 N. Wabash Ave., Chicago 1.

Chicago

Hospital Commemorative Units.—Former members of Passavant Memorial Hospital's medical staff, who had prominent roles in the development of the hospital, will be honored by commemorative units in the new south pavilion. To date the following commemorative units have been organized: Dr. Arthur H. Curtis, professor emeritus of obstetrics and gynecology and former chairman of the department at Northwestern University Medical School and Passavant Hospital, and the late Drs. Marion H. Barker, Sanford R. Gifford, David S. Hillis, and Walter H. Nadler.

Cancer Trust Fund.—The University of Chicago School of Medicine announces receipt of the first income, a $1,000 check, from the Gordon Stephenson trust of $123,325, presented to the university for "cancer research and for the treatment and care of persons afflicted with cancer." The bequest was in the will of the late Gordon Stephenson, former operating superintendent of Sears, Roebuck and Company, an alumnus of the university, who requested that his residuary estate be held in perpetuity and the net income paid to the university. During the first 25 years, the university will receive one-half of the net income with the other half added to the principal of the fund.

IOWA

Pediatrics Conference at Iowa City.—The State University of Iowa College of Medicine, Iowa City, announces a postgraduate conference in pediatrics, Sept. 16-17, sponsored jointly by the department of pediatrics, Iowa Pediatric Society, Maternal and Child Health Division of the State Department of Health, and the State University of Iowa Council on Children and Youth. The Philip C. Jeans memorial program will be presented at 1:30 p. m. Thursday, when remarks will be made by Dr. Jean V. Cooke, Washington University School of Medicine, St. Louis, Leonard A. Maynard, Ph.D., Cornell University, Ithaca, N. Y., and Dr. James R. Wilson, secretary of the A. M. A. Council on Foods and Nutrition, Chicago. At 4 p. m. there will be a eulogy of Dr. Jeans and dedication of the pediatric library in his memory. Other guest speakers at the conference include:

Madelene M. Donnelly, Des Moines, Stillbirths and Neonatal Deaths in Iowa.
Frederick C. Blodi, Iowa City, Pathogenesis of Retrolental Fibroplasis.
James B. Arey, Philadelphia, Pathologic Lesions Responsible for Respiratory Disturbances in the Newborn.
Edmund G. Zimmerer, Des Moines, The State Department of Health and the Welfare of Children in Iowa.
Ralph Bowen, Houston, Texas, Allergy in Identical Twins.
Harold E. Stadler, Indianapolis, Heredofamilial Cerebral Degeneration in Infancy: The Relationship of Systematic Factors to the Pathogenicity.
Ralph Spaeth, Chicago, Tetanus or Serum Sickness.
Charles U. Lowe, Buffalo, Some Effects of Cortisone and ACTH upon Cellular Metabolism.

KANSAS

Chest Physicians Organize.—The recently organized Kansas chapter of the American College of Chest Physicians has elected the following officers to serve for the first year: president, Dr. Charles Pokorny, Halstead; vice-president, Dr. Arthur L. Ashmore, Wichita; secretary-treasurer, Dr. Carl J. W. Wilen, Manhattan; and program chairman, Dr. E. L. Andre Baude, Topeka. Governor for the state of Kansas is Dr. Charles F. Taylor, Norton. Inquiries regarding membership should be addressed to Dr. Taylor at State Sanatorium for Tuberculosis, Norton.

Personal.—Dr. Geoffrey M. Martin, who has returned to Topeka after a year's postgraduate study at Harvard University, has resumed his duties as director of the division of maternal and child health, Kansas State Board of Health. Dr. Patricia Schloesser, who served as acting director of the

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

division while Dr. Martin was on educational leave, is now with the division as pediatric consultant.——Dr. Philip A. Bearg, Topeka, has been transferred from the division of maternal and child health, where he was a pediatric consultant, to the division of preventable diseases, where he will be in charge of epidemiology.

MARYLAND

Award to Baltimore Sunpapers.—According to the U. S. Department of Health, Education, and Welfare, a "mental health bell," cast from shackles once used to restrain mental patients, was awarded to the Baltimore Sunpapers for their "outstanding service in the fight against mental illness." The award, made by Dr. George S. Stevenson, New York, medical director of the National Association for Mental Health, was based on the papers' five year crusade, which resulted in tripling of the operating budget and appropriation of 20 million dollars for Maryland's mental health hospitals. The Sunpapers, Dr. Stevenson noted, "also gave continuing support to setting up community mental health facilities and to appropriation of funds to maintain these facilities." The bell will be kept on display until Mental Health Week, 1954, when it will be awarded to the newspaper, magazine, radio, or television chain or station that has done most to advance mental health in the preceding year.

MICHIGAN

Carl Mitchell Memorial Chapel.—In recognition of "the outstanding Christian devotion and churchmanship" of the late Dr. Carl A. Mitchell, the official board of the Benton Harbor First Christian Church, of which he was a member and elder for nearly 40 years, has designed a "Dr. Carl A. Mitchell Memorial Chapel" in the church's new educational building. All memorial funds now on hand, presented in honor of Dr. Mitchell, and future contributions to the memorial fund, will be used to furnish the chapel. Dr. Mitchell was instrumental in planning and erecting the present church edifice in 1913.

Personal.—Dr. Clark D. Brooks, Detroit, has retired as a member of the Detroit board of education after serving in that capacity for 14 years and twice as its president. Dr. Brooks, aged 73, has been a surgeon on the staff of Harper Hospital.——Dr. Alfred LaBine, Houghton, was recently honored when the Fourth Degree Assembly of the Copper Country Knights of Columbus named its 50 candidate class for him, terming the initiatory group the "Sir Knight Dr. Alfred LaBine Class." Dr. LaBine has served as president of the Upper Peninsula Medical Society and of the Houghton, Keweenaw, and Baraga County Medical Society, and has been chief of staff of St. Joseph's Hospital in Hancock.——Dr. George N. Petroff, Pontiac, was elected as father-of-the-year by the Pontiac Boys' Club, which awarded him a bronze plaque. Dr. Petroff, who has been active in Boys' Club and Boy Scout work, is physician for Pontiac and St. Michael high schools.——Dr. William R. Storer has been appointed St. Joseph County health director, succeeding Dr. Ernest A. Cook, Corunna, who resigned to accept a similar position in West Virginia. Dr. Storer is making his home at North Twin Beach.——A scroll, signed by 200 tuberculosis patients at Saginaw County Hospital, was presented to Dr. Vladimir K. Volk, Saginaw, hospital superintendent, as a tribute for his role in bringing television into the room of every patient at the hospital. A picnic preceded the ceremony. The event marked the official opening of a recreation area for use by ambulatory patients.

MINNESOTA

Annual Fahr Lecture.—The annual George E. Fahr lecture will be delivered by Dr. William F. Hamilton, professor of physiology, Medical College of Georgia, Augusta, on the University of Minnesota campus in Minneapolis at 8 p. m., Sept. 14. The lecture on "The Physiology of Congestive Failure of the Circulation" will be open to all physicians and investigators. Dr. Hamilton will also participate in the "Symposium on Recent Advances in Cardiovascular Physiology and Surgery" that will be presented by the university and the Minnesota Heart Association, Sept. 14-16.

Southern Minnesota Medical Association.—The annual meeting of the Southern Minnesota Medical Association will be held at St. John's Catholic School, Mankato, Sept. 14. The presidential address by Dr. Helmer J. Nilson, North Mankato, will follow remarks by Dr. Orwood J. Campbell, Minneapolis, president of the Minnesota State Medical Association, at the banquet, Mankato Country Club, 6:30 p. m., after which Dr. Leo G. Rigler, Minneapolis, will present "Medical Tour of India." Other speakers include Drs. John C. Mickelson and William S. Chalgren, Mankato; Harlan A. Alexander, Stanley R. Maxeiner, and Ivan D. Baronofsky, Minneapolis; Donald R. Lannin and Edward J. Richardson, St. Paul; Heinz H. Bruhl, Faribault; Robert F. Mears, Northfield; and Edmund C. Burke, Louis E. Prickman, James M. Stickney, Stephen D. Mills, and Henry W. Dodge Jr., Rochester.

MISSOURI

Cardiac Consultation Clinic.—The first clinical session of the Regional Cardiac Consultation Clinic will be held Sept. 16, 9 a. m., at St. John's Hospital in Springfield. The clinic, which is sponsored by the Greene County Medical Society with the cooperation of the Missouri Heart Association, will be held regularly each Wednesday morning at St. John's Hospital. Patients will be accepted only by referral from their physicians. On termination of the study of the patient at the clinic, a report will be sent to the referring physician. Patients from anywhere in southwest Missouri in need of special consultation and who cannot afford such services through regular channels will be admitted to the clinic without charge. The purpose is diagnosis only. The members of the clinic staff will serve without remuneration. Facilities at St. John's Hospital have been made available to the medical society for this program. Staff appointments are made for a three month period, and, in addition to the active staff, all members of the Greene County Medical Society are considered members of the staff to the extent that they are to be available for consultation as the occasion may arise.

MONTANA

Dr. Danskin Honored.—Dr. Melville G. Danskin, Glendive, a past vice-president of the Montana Medical Association, was honored at a public reception at the Methodist Church after he announced his intention to retire from active practice and move to Billings. Dr. Danskin, who has served about 42 years in Glendive and eastern Montana, was appointed county health officer for Dawson County in 1916 and, with the exception of two years, served in that capacity to June 1. Named physician in charge of the Dawson County Hospital in 1916, he has remained in that position. From 1923 to 1927, he was mayor of Glendive and has served as president of the state health officers' association and as the first president of the local Kiwanis Club.

NEW YORK

Albert Fellowships Established.—The establishment of two fellowships for clinical and experimental research has been announced by the trustees of the Jewish Sanitarium and Hospital for Chronic Diseases, Brooklyn. The fellowships, named in honor of the president of the hospital, Mr. Isaac Albert, will be awarded during the fall of 1953. Applicants should write to Arthur Feigenbaum, hospital superintendent, Rutland Road and East 49th St., Brooklyn.

University News.—Dr. A. Harry Rubenstein, who has been affiliated with the State University of New York College of Medicine at Syracuse since 1925, has been appointed professor and chairman of the department of otolaryngology, and Dr. Robert O. Gregg has been named professor and part-time chairman of the department of surgery.——Dr. Gordon D. Hoople, who has been on the staff since 1926, is now professor emeritus of otolaryngology. Dr. Hoople initiated the first full-time medical service to students at Syracuse University. The new speech and hearing center was recently named in his honor.——Dr. Arthur B. Raffl, who joined the staff in 1926 and became professor of surgery in 1946, has been appointed professor emeritus of surgery.

OHIO

Meeting of Anesthesiologists.—The annual meeting of the Ohio Society of Anesthesiologists will be held at the Wade Park Manor Hotel, Cleveland, Sept. 12. Dr. Perry P. Volpitto, Augusta, Ga., will discuss "Management of Anesthesia in Children" and "Problems of Anesthesia in Operative Obstetrics" and will participate in a symposium on intubation, in which the moderator will be Dr. Rolland J. Whitacre, Cleveland, and the other participants Drs. Lloyd E. Larrick, Cincinnati, and Reynold M. Crane, Cleveland.

General Practitioners Meet in Cleveland.—The annual scientific assembly of the Ohio Academy of General Practice will be held at the Hotel Cleveland in Cleveland, Sept. 16-17. As closing features of the scientific program Dr. Duncan E. Reid, professor of obstetrics, Harvard Medical School, Boston, will discuss "Pregnancy Accidents Associated with Alterations in the Hemostatic Mechanism," and Dr. Jerome W. Conn, professor of internal medicine, University of Michigan Medical School, Ann Arbor, will speak on "Spontaneous Hypoglycemia: Differential Diagnosis and Management." At the banquet in the Grand Ballroom, 7 p. m., Wednesday, Dr. George Crile Jr., Cleveland, will present a movie and talk on "Treasure Hunting Holiday."

Personal.—Dr. Marion A. Blankenhorn, professor of medicine, University of Cincinnati School of Medicine, recently served as professor of medicine pro tem at Georgetown University School of Medicine, Washington, D. C., and acted as director of the educational activities of the department of medicine at Georgetown University Hospital and Georgetown University School of Medicine.——Dr. Carl J. Wiggers, who recently retired as director of the department of physiology, Western Reserve University School of Medicine, Cleveland, has become associated with the Frank E. Bunts Educational Institute affiliated with the Cleveland Clinic Foundation.——Dr. Lawrence H. Miller, Granville, was appointed professor of health education and director of student health services at Denison University.——Dr. Max M. Zinninger, associate professor of surgery, University of Cincinnati College of Medicine, delivered the first George J. Heuer lecture in New York, when Dr. Heuer's portrait was presented to the Cornell University Medical College, of which he is emeritus professor of surgery. Dr. Heuer, who now lives in Rye, N. Y., was professor of surgery at the University of Cincinnati College of Medicine from 1922 to 1931. Dr. Zinninger also gave a talk on "Development of the Resident Training System at the Cincinnati General Hospital" for Pi Kappa Epsilon's annual dinner and initiation of new members in Cincinnati.

PENNSYLVANIA

Fifty Year Plaques.—The Luzerne County Medical Society recently awarded 50 year plaques to Drs. Roy Truckenmiller, Freeland, Harry A. Brown, Lehman, Austin L. Hauslohner, Wilkes-Barre, William C. Stiff, Forty Fort, and Wilbur A. Foster, Mountaintop.

Reorganize Alumni Association.—Graduates of Jefferson Medical College of Philadelphia met recently at the Harrisburg Academy of Medicine to reorganize the South Central Pennsylvania Jefferson Alumni Association that had not met since 1941. Dr. Norman B. Shepler, Harrisburg, was elected president; Dr. Roy W. Gifford, Gettysburg, vice-president, and Dr. Raymond C. Grandon, Harrisburg, secretary-treasurer.

Memorial to Dr. Pennell.—A plaque was recently dedicated in honor of the late Dr. Howard Y. Pennell by the x-ray department of the Chester County Hospital, West Chester. Dr. Pennell, who died in 1952, had been associated with the hospital for 54 years; he came there as its first intern. He later became a permanent staff member and director of the x-ray department, which he founded in 1909. Among those participating in the dedicatory ceremonies were Arthur E. James, Ph.D., and Drs. Jacob Gershon-Cohen, Philadelphia, and Louis S. Bringhurst, West Chester.

Appoint Superintendent of Sanatorium.—Dr. Sterling B. Brinkley, Johnstown, will become medical superintendent of the Gaylord Farm Sanatorium in Wallingford, Conn., Oct. 1. He succeeds Dr. David Russell Lyman who, 50 years ago, became the original head of the sanatorium and who will now become medical superintendent emeritus. Dr. Brinkley has been affiliated with the Gorgas Hospital, Ancon, Canal Zone, the Cornell University Medical College, New York, and Yale University, New Haven, Conn. He is a director of the Pennsylvania Tuberculosis and Health Society and of Yale in China and is vice-president of the Pennsylvania Rehabilitation Association. Dr. Brinkley was commanding officer of an infantry division-collecting company in the European theater for two years.

Philadelphia

University News.—Dr. William T. Lemmon has been made a full professor of medicine at Jefferson Medical College of Philadelphia. He had been clinical professor of surgery and served also as assistant professor of applied anatomy.

Meeting on Cytology.—The first annual meeting of the Inter-Society Cytology Council will be held in Philadelphia Nov. 19-20. Those interested in presenting papers pertaining to the cytological method for the diagnosis of cancer and related subjects are urged to send titles, together with an abstract of not more than 300 words, to the chairman of the program committee, Dr. Abraham E. Rakoff, Jefferson Medical College, 1025 Walnut St., Philadelphia 3.

Personal.—Dr. William M. Hart, assistant professor of ophthalmology, Jefferson Medical College of Philadelphia, has been appointed chief of the ophthalmology clinics of the National Institute of Neurological Diseases and Blindness, Public Health Service, Bethesda, Md.——Dr. Garfield G. Duncan left July 30 for a teaching tour in New Zealand and Australia. He will head a three week course in internal medicine under the auspices of the New Zealand Post-Graduate Association in Auckland and will deliver the Cunning memorial lecture on "Undernutrition as Encountered in General Practice" before the Royal Australasian College of Physicians at Dunedin. In Australia he will lecture on "Essential Hypertension" at Sydney.

TENNESSEE

Anonymous Gift to Vanderbilt University.—Dr. John B. Youmans, dean, Vanderbilt University School of Medicine, Nashville, announces that an anonymous donation of $40,000 will be used to establish a laboratory for clinical microbiology. It is anticipated that an additional sum of $15,000 a year for four years soon will be made available from the same source. The laboratory will be under the departmental supervision of Dr. Hugh J. Morgan, head of the department of medicine.

TEXAS

Postgraduate Courses.—The Houston division of the University of Texas Postgraduate School of Medicine offers a 6 week course in diabetes on Tuesday evenings, beginning Sept. 15; a 6 week course in acute infectious diseases Tuesday evenings, beginning Nov. 10; wet surgery clinics for 10 weeks on Friday mornings, beginning Sept. 25; and a 12 week series on cardiology and electrocardiography on Monday evenings, beginning Sept. 28 in Austin. The San Angelo division will hold medical conferences each Sunday, beginning the latter part of September. Information may be obtained from the Dean, University of Texas, Postgraduate School of Medicine, 1400 Outer Belt Drive, Houston 25.

North Texas-Southern Oklahoma Conference.—The program of the North Texas-Southern Oklahoma Fall Clinical Conference will be presented by members of the staff of Johns Hopkins University School of Medicine, Baltimore, at the Wichita Falls Country Club in Wichita Falls Sept. 16. For the morning session Dr. Jack S. Guyton, professor of ophthalmology, will present "Treatment of Squint," Dr. Samuel P. Asper, associate professor of medicine, "Clinical Use of Cortisone and ACTH," and Dr. Alan C. Woods Jr., instructor, "Surgical Treatment of Complications of Cirrhosis." After luncheon followed by a round-table question and answer period, Dr. Asper will speak on "Newer Aspects in Treatment of Thyroid Diseases," Dr. Woods on "Surgical Treatment of Cancer of the Thyroid," and Dr. John T. Grayhack of the Johns Hopkins Hospital staff on "Diagnosis and Treatment of Operable and Inoperable Prostatic Cancer." Dinner at 7:30 p. m. will be preceded by a cocktail hour. The registration fee, $8, includes luncheon, dinner, scientific programs, and entertainment; ticket for lady guest for dinner and the evening program, $4. Address inquiries to Dr. L. Nolan Simmons, 1518 10th St., Wichita Falls.

WEST VIRGINIA

Personal.—Dr. Frank J. Holroyd, Princeton, has been elected president of the state medical licensing board. He succeeds Dr. Walter E. Vest, Huntington, who has been president since the creation of the board in 1949.

Annual Seminar at Bluefield.—The Bluefield Sanitarium will hold its first annual clinical seminar in the staff room, Oct. 2. Discussion periods and exhibits by the departments of urology, clinical pathology, neurosurgery, roentgenology, and ophthalmology and otolaryngology will be included in the program. Guest speaker at the banquet at the Bluefield Country Club will be Dr. George T. Harrell Jr., professor of medicine, Bowman Gray School of Medicine, Winston-Salem, N. C., who will discuss "Myxedema."

WISCONSIN

Diabetes Forum.—The fall postgraduate program at the Marquette University School of Medicine, Milwaukee, will open Sept. 19 with a one day forum in diabetes mellitus, which will be presented by the medical school in cooperation with the Wisconsin Diabetes Association. Dr. William W. Engstrom, associate professor of medicine, will direct the forum. Dr. Francis R. Keating Jr., consultant in medicine, Mayo Clinic, Rochester, Minn., is to be guest speaker. Reservation for the day, which includes luncheon, should be made through the Director of Postgraduate Programs, Marquette University School of Medicine.

HAWAII

Personal.—Dr. Charles L. Wilbar Jr. for 10 years president of the Hawaii Territorial Board of Health, has been appointed assistant health executive of the State of Pennsylvania. Dr. Richard K. C. Lee, assistant health executive of the Hawaii Territorial Department of Health since 1943, and prior to that deputy commissioner of public health since 1937, will succeed Dr. Wilbar as president of the board of health.

Industrial Health Meeting.—The meeting in Honolulu of the Territorial Association of Plantation Physicians, a component society of the Industrial Medical Association, heard Dr. George F. Wilkins, Boston, Industrial Medical Association president, give an address on "The Future of Industrial Medicine." Dr. Earl F. Lutz, Detroit, associate medical director, General Motors, discussed "Health Plans in Big Industry." At the industrial medicine and medical economics panel luncheon, Dr. William H. Wilkinson, Wahiawa, served as moderator, and Drs. Lutz, Edward C. Holmblad, Chicago, Leo Price, New York, Frank Hatlelid, Waialua, Sam Wallis, Lihue, J. Alfred Burden, Paia, and Francis J. Halford, Honolulu, were among the panel participants.

Surgical Wing at Queen's Hospital.—The public subscription campaign to raise the final $600,000 needed to provide a new surgical wing at the Queen's Hospital, Honolulu, was recently concluded. First to memorialize sections of the new building was a retired physician, Dr. Tang L. Wong, who gave $10,000 under a new living memorial plan developed by hospital officials. The total cost of the entire development at the institution will be about $1,400,000. In addition to 14 new operating rooms, a 12 bed postoperative recovery ward, and an auditorium seating 80, the new wing allows the removal of the pediatric unit into fire-resistant quarters and inclusion of an isolation unit, use of former operating rooms as an expanded laboratory with additional research rooms, addition of 106 new beds with replacement of 84 declared unacceptable, and removal of the outpatient clinic to largely expanded quarters in older wings. Dr. Forrest J. Pinkerton headed the solicitation of funds from professional groups in the islands.

GENERAL

Appoint Medical Adviser.—American Leprosy Missions, Inc. (156 Fifth Ave., New York 10) announce the appointment of Robert G. Cochrane, M.D. (Glas.), F.R.C.P. (Lond.), D.T.M. & H. (Eng.), as technical medical adviser. His services will be available to all physicians working in leprosy colonies or clinics connected with Protestant missions and to any others who may solicit his advice. Dr. Cochrane will continue for the present to maintain an office and a laboratory in London but will make periodic trips to Asia, Africa, South America, and the United States.

Antibiotics Award.—At the annual convention of the Society of American Bacteriologists in San Francisco, the 1952 Commercial Solvents Award in Antibiotics, consisting of a gold medal, $1,000, and engraved scrolls, was presented to Ibert C. Wells, Ph.D., Syracuse, N. Y., Edwin E. Hays, Ph.D., Chicago, Dr. Edward A. Doisy, St. Louis, and William L. Gaby, Ph.D., Philadelphia, for their work with Pseudomonas aeruginosa. Their 10 years of research, started at St. Louis University in the early days of World War II, demonstrated that in addition to pyocyanine, Pseudomonas aeruginosa produces several other antibacterial agents. The group worked out methods of isolation, separation, and purification of these agents, defined their physical and chemical properties, proposed structural formulas for them, and, by degradation and synthesis, proved the acceptability of the proposed formulas.

North Pacific Internal Medicine Meeting.—The North Pacific Society of Internal Medicine will hold its annual fall meeting at Harrison Hot Springs, B. C., Canada, Sept. 18-19. The evening preceding the meeting there will be cocktails and a reception, 6-7 p. m. The scientific program is as follows:

Charles N. Holman, Portland, Ore., The New General Hospital at the University of Oregon Medical School.

Joseph H. Delaney, Spokane, Wash., Thyrotoxic Heart Disease.

Russell B. Hanford, Spokane, Wash., Are Vagal Inhibitors of Use in Treatment of Intermittent Atrioventricular Block?

Ralph H. Huff, Tacoma, Wash., Clinical Conditions Simulating Coronary Artery Disease.

Kyran R. E. Hynes, Seattle, Significance of Cardiac Vectors.

Raymond A. McMahon, Portland, Ore., Observations on the Conducting System of Congenital Heart Cases.

E. Murray Burns, Portland, Ore., Emulsifying Agents in Digestive Disorders.

Robert H. Williams, Seattle, Recent Advances Relative to Diabetes.

Hamish W. McIntosh, Vancouver, B. C., Observations on the Electrolyte Metabolism in Stress.

Earl D. DuBois, Portland, Ore., Diagnosis and Treatment of Disturbances Arising from the Sphincter of Oddi.

George A. Boylston, Portland, Ore., Peptic Ulcer of the Pyloric Ring.

Cardiac Grants-In-Aid.—On its fifth anniversary as a voluntary health agency, the American Heart Association announced that, jointly with its affiliates, it had awarded an additional $473,930.59 for 89 research grants-in-aid in the field of heart and blood vessel diseases. The latest awards increase to a grand total of almost 6.5 million dollars the sums spent for research studies by the American Heart Association and its affiliated state and local associations over the five year period. Of the continued grants the largest went to Samuel Gurin, Ph.D., University of Pennsylvania School of Medicine, Philadelphia, $10,500 (how cholesterol and fats are built up by the body with special regard to the role of hormones in this process), and Dr. Albert Szent-Gyorgyi, Marine Biological Laboratories, Woods Hole, Mass., $10,000 (further studies on the molecular changes that occur within muscle during muscular contraction). Highest grants for new projects were awarded to Bernardo A. Houssay, Instituto de Bioligia y Medicina Experimental, Buenos Aires, Argentina, $10,000 (studies on experimental high blood pressure); James D. Ebert, Indiana University School of Medicine, Bloomington, $9,607.50 (the study of two substances, actin and myosin, thought to be important in the work of the heart muscle); and Dr. John J. Osborn, New York University-Bellevue Medical Center, $8,268.75 (use of refrigeration and of a heart-lung machine in temporarily interrupting the circulation to facilitate surgery).

Western Tuberculosis Conference.—The first meeting of the Western Tuberculosis Conference will be held at the Hotel Utah, Salt Lake City, Sept. 17-19. The general sessions will open Thursday, 2 p. m., with a discussion of Indian health problems, after which Dr. Lloyd K. Swasey, Phoenix, Ariz., will serve as chairman for a discussion of "Laws Regarding Sanatorium Care and Isolation of Patients." On Friday morning, which will be devoted to clinics, Dr. Francis J. Weber, Denver, will be chairman for "Future Responsibility of the State and Local Health Departments in Tuberculosis Control Activities" and Dr. Terrell O. Carver, Boise, Idaho, for "The Tuberculosis Control Program in Low Prevalence Areas—In Sparsely Populated Areas." After luncheon Dr. Daniel W. Zahn, Seattle, will preside at the general session. The banquet at 7 p. m. in the Empire Room will be followed by a general session, with Dr. John Z. Bowers, Salt Lake City, presiding. Saturday morning Dr. William H. Oatway Jr., La Vina, Calif., will speak on "Implications of Advances in Medical Diagnosis and Treatment," and Dr. Sidney H. Dressler, Denver, will present "The Denver Study in Retrospect." Dr. George Jacobson, Los Angeles, will address the general session at luncheon Saturday, 12:30 p. m., on routine roentgenograms of general hospital admissions. A special medical session will be held Friday in the Little Theatre, where the following presentations will be made:

John H. McClement, Salt Lake City, Cardiopulmonary Function in Pulmonary Sarcoidosis.
Thomas H. Holmes III, Seattle, Stress and Tuberculosis.
John W. Berry, James C. Bell, and Dick K. Riemensnider, Denver, Place of Slide Culture in Pulmonary Tuberculosis and Suspected Tuberculosis.
Gardner Middlebrook, Denver, Bacteriology of Tuberculosis.
Maxwell M. Wintrobe, Salt Lake City, Anaemia of Infection.
William S. Conklin, Portland, Ore., Surgical Trends in Pulmonary Tuberculosis.
William H. Oatway Jr., La Vina, Calif., Subject to be announced.

Annual Clinicians Meeting in Chicago.—The annual session of the American Association of Medical Clinicians will be held at the Congress Hotel, Chicago, Oct. 9-11, under the presidency of Dr. Clair L. Stealy, San Diego, Calif. The sessions will open Saturday, 10 a. m., with a panel on "Prepaid Medical Care Plans: Status and Problem," for which Dr. Wayne Gordon, Billings, Mont., will serve as moderator. The presidential address and an address by Dr. Alton Ochsner, New Orleans, will be delivered at the luncheon, 12:30 p. m. A cocktail party, courtesy of Marshall Field Clinic, will follow the afternoon business session. Dr. Edwin P. Jordan, Charlottesville, Va., executive director of the association, will address the professional problems session, Sunday, 9:30 a. m., on "Professional Composition of Group Practices." Dr. R. Franklin Jukes, Akron, Ohio, will be moderator for a panel on "Problems in Internal Structure and Organization of Clinics" at 9:50 a. m., and Dr. Charles V. Edwards, Council Bluffs, Iowa, will moderate a panel discussion on "Physician's Role in Clinic Personnel Policies" at 11 a. m. Mr. Leo E. Brown, Director, A. M. A. Department of Public Relations, will be guest speaker at the luncheon, 12:30 p. m., and will discuss "PR Profits vs. Dollar Profits." At 2:20 p. m. "Should Clinics Require Staff Members to Sign Agreements Restricting Their Right to Practice in the Community" will be presented by Dr. Harold D. Caylor, Bluffton, Ind., and Mr. George E. Hall of the A. M. A. Bureau of Legal Medicine and Legislation.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

CANADA

Anesthesia Research Meeting.—The International Anesthesia Research Society will meet at the Chateau Frontenac, Quebec, Oct. 26-29. Dr. A. William Friend, Akron, Ohio, will serve as moderator Thursday morning for a panel discussion on "Further Evaluation of Elective Hypotension as an Adjunct to Surgery." Participants will include Drs. Charles R. Stephen, Ruth C. Martin, and William K. Nowill, Durham, N. C., who will present "Production of Controlled Hypotension During Surgery with Pendiomide," Dr. Max S. Sadove, Chicago, who will discuss "Arfonad and True Controlled Hypotension," and Drs. Nicholas M. Greene, Rochester, N. Y., C. Paul Boyan, New York, and David M. Little Jr., New Haven, Conn. Thursday afternoon Dr. Morris J. Nicholson, Boston, will be moderator for a panel on "Hospital Hazards and Their Control," with Drs. D. Dwight Grove, Philadelphia, and George J. Thomas, Pittsburgh, as collaborators.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec. 1-4.
1954 Annual Meeting, San Francisco, June 21-25.
1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Meeting, Atlantic City, N. J., June 6-10.
1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

NATIONAL CONFERENCE ON PHYSICIANS AND SCHOOLS, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

AMERICAN ACADEMY FOR CEREBRAL PALSY, Western Hills Hotel, Fort Worth, Texas, Oct. 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

AMERICAN ACADEMY OF PEDIATRICS, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

AMERICAN ASSOCIATION OF BLOOD BANKS, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

AMERICAN ASSOCIATION OF MEDICAL CLINICS, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

AMERICAN ASSOCIATION OF MEDICAL RECORD LIBRARIANS, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

AMERICAN ASSOCIATION FOR THE SURGERY OF TRAUMA, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

AMERICAN CANCER SOCIETY, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

AMERICAN CLINICAL AND CLIMATOLOGICAL ASSOCIATION, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

AMERICAN COLLEGE OF SURGEONS, Conrad Hilton Hotel, Chicago, Oct. 5-9. Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

AMERICAN DENTAL ASSOCIATION, Cleveland, Sept. 28-Oct. 1. Dr. Harold Hillenbrand, 222 E. Superior St., Chicago 11, General Secretary.

AMERICAN FRACTURE ASSOCIATION, Mission Inn, Riverside, Calif., Oct. 12-15 Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

AMERICAN MEDICAL WRITERS' ASSOCIATION, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

AMERICAN ROENTGEN RAY SOCIETY, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* All centers where there are five or more candidates. Sept. 8-10 (Part I only). Candidates may file applications at any time, but the National Board must receive them at least six weeks before the date of the examination they wish to take. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16, 1954. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: All candidates must now pass a written examination. *Oral.* Philadelphia, Oct. 16-18. To be eligible, candidate must complete 36 months of training before Oct. 1. Final date for filing applications was May 1. Exec. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Sept. 30-Oct. 2, Chicago, Nov. 30-Dec. 2. The closing date for acceptance of applications for the San Francisco and Chicago oral examination was April 1. *Written.* October 19. The closing date for acceptance of applications was May 1. Exec. Sec.-Treas., Dr. William A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* New Haven, October. Final date for filing application was July 1, Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, Kingshighway and Euclid Ave., St. Louis.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: *Written.* Various cities of the United States and Canada, Feb. 5. Application for examination or re-examination, as well as requests for resubmission of case reports, must be made prior to October 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: Chicago, Oct. 5-9. *Written.* Various Centers, January 1954. Final date for filing applications was July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written. Pathologic Anatomy and Clinical Pathology.* Chicago, Oct. 8-10. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Miami, Oct. 9-11; Indianapolis, Dec. 4-6. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Entire Examination.* San Diego, Oct. 29-31. Final date for receipt of case reports was June 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Proctology: *Part II. Oral and Written. Anorectal Surgery and Proctology.* Philadelphia, Sept. 19. Sec., Dr. Louis A. Buie, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Surgery: *Part I.* Oct. 28, 1953. March 31, 1954 and Oct. 27, 1954. *Part II.* New York City, Oct. 12-13; Chicago, Nov. 9-10; St. Louis, Dec. 14-15; Los Angeles, Jan. 11-12, 1954; Galveston, Jan. 15-16; Washington, Feb. 8-9; Cincinnati, March 8-9; New Orleans, April 12-13; Philadelphia, May 10-11; Boston, June 14-15. Sec., Dr. John B. Flick, 225 S. 15th St., Philadelphia 2.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 11. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

DEATHS

Metz, Waldemar Rice ⊕ New Orleans; born in New Orleans in 1891; Tulane University of Louisiana School of Medicine, New Orleans, 1913; clinical associate professor of surgery, Louisiana State University School of Medicine; specialist certified by the American Board of Plastic Surgery; member of the Southeastern Surgical Congress and the American Society of Plastic and Reconstructive Surgery; fellow of the American College of Surgeons; past president and vice-president of the Orleans Parish Medical Society; one of the founders, member of the board, and past president of the New Orleans Graduate Medical Assembly; served during World War I; plastic surgeon for the crippled children's division, state board of health; formerly associated with the U. S. Public Health Service; consultant plastic surgeon, U. S. Public Health Service Hospital, Carville, La.; attending plastic surgeon, U. S. Public Health Service Hospital; member of the staffs of Southern Baptist Hospital, Mercy Hospital-Soniat Memorial, Sara Mayo Hospital, Charity Hospital of Louisiana, and Touro Infirmary, where he died July 10, aged 62, of cerebral embolism with massive infarction of left cerebral hemisphere.

Walker, Alfred Augustus ⊕ Birmingham, Ala.; born in 1881; Cornell University Medical College, New York, 1905; emeritus professor of pediatrics at Medical College of Alabama; member of the House of Delegates of the American Medical Association from 1924 to 1926, in 1930, from 1934 to 1945, and in 1948, a member of its Council on Scientific Assembly from 1935 to 1945, serving as chairman of the council from 1942 to 1945, and secretary of the Section on Diseases of Children from 1930 to 1933 and chairman, 1933-1934; for many years chairman of the Jefferson County Board of Health; a director of the American Board of Pediatrics from 1934 to 1944; member of the American Academy of Pediatrics; served during World War I; affiliated with Children's Hospital, St. Vincent's Hospital, and Jefferson-Hillman Hospital; consultant in pediatrics at South Highlands Infirmary; died in St. Vincent's Hospital July 7, aged 72, of congestive heart failure, myocardial infarction, and arteriosclerosis.

Griffith, William Allen, Berwyn, Md.; College of Physicians and Surgeons, Baltimore, 1909; at one time physician at the University of Maryland in College Park; served during World War I; past president of the Prince Georges County Medical Society, Southern Maryland Medical Society, and the state board of medical examiners; formerly director of Prince Georges Bank and Trust Company; for 34 years local physician for the Baltimore and Ohio Railroad; on the staff of Leland Memorial Hospital in Riverdale, where he died June 16, aged 72, of cerebral hemorrhage.

Ball, Otho Fisher ⊕ Chicago; St. Louis College of Physicians and Surgeons, 1897; member of the American College of Hospital Administrators; president of the Modern Hospital Publishing Company, publishers of *Modern Hospital;* died July 19, aged 78, of coronary occlusion.

Best, Alonzo Lee, Newport, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; died July 11, aged 78.

Bollmeier, Ludolf Nicholas ⊕ Hot Springs National Park, Ark.; St. Louis College of Physicians and Surgeons, 1921; Kansas City (Mo.) College of Medicine and Surgery, 1922; member of the American Psychoanalytic Association, American Psychosomatic Society, American Psychiatric Association, and the Association for Research in Nervous and Mental Diseases; consultant at Veterans Administration Hospital in North Little Rock; died in St. Joseph's Infirmary July 6, aged 54, of acute coronary occlusion.

Brown, Frederick Willard, Dwight, Ill.; Chicago College of Medicine and Surgery, 1911; died in Veterans Administration Hospital July 12, aged 71.

Crowe, John William ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1897; died in Montgomery County, Md., July 18, aged 85, of generalized arteriosclerosis.

Downing, Perley Edwin, Trenton, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1914; senior resident physician, New Jersey State Hospital; died in Tremont, Pa., July 12, aged 67, of cerebral thrombosis.

Foster, Herbert West ⊕ Montclair, N. J.; New York Homeopathic Medical College and Hospital, New York, 1891; an Associate Fellow of the American Medical Association; founder and first president of the Associated Physicians of Montclair and Vicinity; served on the staffs of the Mountainside and Montclair Community hospitals; died July 13, aged 83, of pneumonia and emphysema.

Heil, Ulysses S. Grant, Easton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; died in Betts Hospital July 17, aged 85.

Lewis, Margaret C., Honey Brook, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; died in West Chester, July 13, aged 84, of cerebral hemorrhage.

McCastline, William Henry ⊕ Brandon, Vt.; Columbia University College of Physicians and Surgeons, New York, 1903; member of the Medical Society of the State of New York; for many years medical officer at Columbia University; died July 11, aged 77, of coronary thrombosis.

Milligan, Leo Patrick, Huntsville, Ala.; Georgetown University School of Medicine, Washington, D. C., 1911; died July 8, aged 69, of cerebral hemorrhage.

Murphy, Eugene Clement ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1913; fellow of the American College of Surgeons; served in France during World War I; formerly affiliated with the U. S Public Health Service; on the staff of the Doctors Hospital, of which he was one of the founders, and St. Agnes Hospital; died July 9, aged 62, of pulmonary tuberculosis.

Palay, Lewis, Miami Beach, Fla.; University of Louisville (Ky.) School of Medicine, 1928; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the American College of Allergists; affiliated with Mount Sinai Hospital, where he died July 17, aged 51, of coronary thrombosis and myocardial infarction.

Pascall, Thomas Myrick ⊕ Newark, N. J.; Baltimore Medical College, 1906; member of the Industrial Medical Association; died in Hospital of St. Barnabas and for Women and Children July 17, aged 72, of cerebral thrombosis.

Peeler, Crawford Monroe ⊕ Pangburn, Ark.; University of Nashville Medical Department, 1909, past president of the White County Medical Society; served as mayor of Pangburn; died in Searcy July 7, aged 72, of coronary occlusion.

Plumlee, Claude Hamilton, Celina, Tenn.; University of Tennessee College of Medicine, Memphis, 1952; interned at John Gaston Hospital at Memphis; died July 5, aged 30, of injuries received in an automobile accident.

Purvey, John Compton ⊕ Crystal Lake, Ill.; University of Illinois College of Medicine, Chicago, 1939; served during World War II; affiliated with St. Joseph and Sherman hospitals in Elgin, and the Memorial Hospital in Woodstock; died in Augustana Hospital, Chicago, July 14, aged 39, of subdural hemorrhage.

Roberts, David William, Okemos, Mich.; Cleveland University of Medicine and Surgery, 1897; affiliated with Edward W. Sparrow Hospital in Lansing; for many years medical director of the Ingham County Hospital; died July 29, aged 87, of cerebral hemorrhage.

⊕ Indicates Member of the American Medical Association.

GOVERNMENT SERVICES

ARMY

Regular Army Physicians May Now Resign.—Regular officers of the Army Medical Service may resign and leave the service under a new and more liberal Department of the Army policy, according to Major Gen. Siles B. Hays, Acting Surgeon General. Beginning with officers having the longest periods of service, a number will be allowed to resign each month, on recommendation of the Surgeon General, provided they have met certain service requirements. Previously, resignations were accepted only in cases of extreme hardship. According to the new policy, regular officers who have no obligatory commitments to the Army and who have served in the Regular Army for a period of three years are eligible for release. If, however, they have served for less than eight years, they must accept commissions in the Reserve.

"Even though we expect to lose some officers in the next few months," General Hays said, "we believe the new policy will encourage physicians to enter the Regular Army because they will no longer be required to commit themselves to an indefinite term of service. Actually, I believe that our increasing percentage of officers will find the military service so stimulating professionally and so pleasant that they will make it their career."

NAVY

Medical and Dental Symposium.—The third medical and dental military symposium under the auspices of the First Naval District will be held at the Naval Hospital, Chelsea, Mass., October 12-14. Civilian physicians, dentists, and members of allied sciences, in addition to those of the armed forces, are invited to attend. The subjects will be presented by speakers of outstanding prominence in their specialties.

The Chief of Naval Personnel has approved the symposium for retirement point credit for Reservists not on the Inactive Status List. One retirement point credit will be awarded for each of the three sessions attended providing the duration of the meeting is at least two hours. Requests for duty orders should be submitted to the Commandant of the First Naval District.

PUBLIC HEALTH SERVICE

Conference of Foreign Health Workers.—About 85 foreign health workers who have received postgraduate training in the United States through the assistance of the Division of International Health, Public Health Service, met in Washington August 17-21 for an evaluation seminar. During the week-long conference, the group had an opportunity to discuss their experiences in the nine months of academic training and three months of field training just completed. The trainees, who have been studying public health, nursing education, public health nursing, sanitary engineering, and various clinical fields, represent 20 different countries: Thailand, Burma, India, Brazil, Colombia, Costa Rica, Finland, Germany, Greece, Honduras, Indonesia, Iraq, Lebanon, Mexico, Panama, Philippine Islands, Taiwan, Uruguay, and Vietnam. The students carried out their work in the United States under the sponsorship primarily of the Technical Cooperation Administration, the Mutual Security Agency, and the Office of the High Commissioner of Germany. They were placed by the Division of International Health in 28 universities, hospitals, and laboratories throughout the country.

Applications for Hospital Construction.—By the end of June 30, 1953, a total of 2,104 applications for hospital construction had been approved under the terms of the Hill-Burton Act, according to the Division of Hospital Facilities, Public Health Service. More than 1,200 of the projects are open and in operation, 727 are under construction, and the remaining are in preconstruction stages. These projects will add 102,362 hospital beds and 413 health centers to the nation's health facilities at a cost of more than one and two-thirds billion dollars. The federal government is contributing over 500 million dollars and the sponsors more than one billion dollars. The majority of all approved applications (71%) are for general hospital projects; 4% are for mental hospitals, 3% for tuberculosis hospitals, and 2% for chronic disease facilities. Of the total projects, 1,242, or 59%, are completely new facilities; additions or alterations to existing facilities comprise the remaining 41%.

Water Pollution Control.—The nation's municipalities invested about 31 million dollars in water pollution control projects during the first quarter of 1953, the Public Health Service has announced. Contracts were awarded for 119 sewage treatment projects designed to keep harmful wastes out of rivers, lakes, and other waterways. Of these, 61 were for construction of new sewage treatment plants, 48 for enlargement or improvement of existing plants, and 10 for construction of interceptor sewers. Dr. Leonard A. Scheele, Surgeon General of the Public Health Service, said the 31 million dollar investment represents a slight increase over last year's expenditures for the comparable period but is far below the amount needed to conserve the nation's clean water resources. Many more cities and towns need to follow the example of these 119 municipalities in solving their own local problems, if the total national problem is to be solved.

Personal.—Dr. Stanley E. Krumbiegel has been appointed medical officer in charge of the U. S. Public Health Service Outpatient Clinic at Washington, D. C., to succeed Dr. Clifton K. Himmelsbach, recently assigned as assistant chief, division of hospitals, Public Health Service. In his new position, Dr. Krumbiegel, who since 1948 has been medical director of the Bureau of Prisons, Department of Justice, will be responsible for the administration of the medical care program for beneficiaries of the Public Health Service in the Washington area. Dr. Harold M. Janney, who since 1950 has been medical director of the U. S. Penitentiary, Atlanta, Ga., has been appointed medical director of the Bureau of Prisons. The Public Health Service administers the medical care, health, and hospital activities in federal penal and correctional institutions.

VETERANS ADMINISTRATION

New Hospital Managers.—The Veterans Administration has announced the appointment of managers for the VA neuropsychiatric hospitals at Danville, Ill., and Roseburg, Ore. Dr. Oreon K. Timm, chief of professional services at the 1,700-bed Danville hospital, will become manager of that institution, succeeding Dr. L. E. Trent who is retiring Sept. 30, 1953. Dr. George L. Wadsworth, chief of professional services at the VA Hospital in Tomah, Wis., will become manager of the 577-bed hospital at Roseburg, succeeding Dr. John L. Haskins, who has been transferred to the VA center at Los Angeles. Dr. Glen W. Doolen, chief of plans and development in the tuberculosis division of the department of medicine and surgery, Washington, D. C., has been appointed manager of the VA Hospital at Richmond, Va. He will succeed Dr. John G. Hood, who has been transferred to the VA Hospital, Bronx, N. Y., where he will be manager.

FOREIGN LETTERS

ARGENTINA

Chagas' Disease.—The American human trypanosomiasis caused by Trypanosoma cruzi was discovered by Carlos Chagas in Brazil. For some time, the importance of the disease was minimized, but Salvador Mazza, in Argentina, demonstrated that the disease is endemic over wide areas. The importance of the chronic myocardial diseases was recognized by Mazza (province of Jujuy) and by Cecilio Romaña (province of Tucumán). The diagnosis of acute cases was facilitated by the recognition of an unilateral palpebral edema (Romaña sign). The diagnosis is established by three methods: (1) direct examination of a thick drop of blood; (2) by xenodiagnosis, with blood secured in the suspected case by triatomas bred in the laboratory free of crithidias; and (3) by the Machado-Guerrero seroreaction.

The disease is transmitted by the bite of Triatoma infestans, which is usually found in rural houses. The Triatomas are found from Patagonia (Argentina) to the southern United States. Triatoma infestans, the principal vector in Argentina, is infected by Trypanosoma cruzi in large but variable proportions. The proportion of children infected is from 6 to 40%, and it is believed that 15 to 20% of the rural population have been infected by the Trypanosoma organisms. If this is so, 500,000 or more of the 3,500,000 inhabitants who have been in contact with triatomas have been infected with a Trypanosoma.

The Ministry of Public Health held a conference on trypanosomiasis in the last week of June. A special department of the Ministry of Health, under the direction of Dr. Cecilio Romaña, is in charge of prevention of this disease. The fight against the Triatoma insects is based on (1) making houses insect-proof and (2) use of insecticides, DDT, and fumigation with smoke containing DDT. Results of the preliminary trials of these methods have been very gratifying.

Mortality of Young Rats at Mountain Heights.—In the Institute of High Altitude Biology organized by the University of Tucumán in Mina Aguilar (province of Jujuy) at 3,990 m. (12,000 ft.), Dr. Hugo Chiodi (director of the Institute) observed interesting facts on the mortality of young rats in the first days of life. According to Monge (in Peru), in the first Spanish settlement in Potosí, men and animals living in the high mountain could not have descendants. Chiodi observed that only 7 young rats out of 46 newly born at mountain heights could survive more than 30 days and they died at 38, 42, 45, and 100 days of age.

The mortality of 436 newly born rats was 35% in the first three days. The causes of death were liver damage and fatty degeneration. The animals survived when they were maintained at the same altitude with the same food for 30 days and when the oxygen pressure was similar to that of sea level.

When the animals reached 30 to 40 days of age, they survived well under the same conditions. The danger was only for rats younger than one month. Older rats showed no hepatic lesions and survived without apparent disturbances.

Second Argentina Congress of Gastroenterology.—The Second Congress of Gastroenterology was held in Mar del Plata, April 14-18. Abnormalities of the stomach found at operation were the subject of the reports and discussions. The subject was considered from the standpoint of hematological variations, physiopathology, radiology, gastroscopy, gastric ulcers, gastrointestinal pathology, biliary pathology, endocrine effects, and dietetic treatment. The president of the congress was Dr. Marcelo Royer. Guests of honor were the German professor Dr. Henning and some Brazilian physicians. Representatives of the Argentine gastroenterological centers attended the meetings, which were very successful.

AUSTRALIA

Typhoid Epidemic Traced to Unusual Cause.—In Victoria, New South Wales and Australian Capital Territory, an epidemic of typhoid developed last June, and the total number of cases to date is 56, of which 28 occurred in New South Wales and 24 in Victoria. An investigation of all the usual sources failed to elucidate the cause. The scattered incidence seemed contrary to usual experience. At Moorabbin, a suburb 11 miles (17.7 km.) from Melbourne, the senior health inspector, Mr. N. T. Davies, was persistent in questioning families infected. He was seeking a common food item that was eaten raw but that would store well and that could be distributed over a wide area.

The first clue came from two infected families who admitted a fondness for "Snowballs." These are confections made from artificial marshmallow (gelatin) and rolled in desiccated coconut. In a third family, Mr. Davies found some homemade cookies rolled in desiccated coconut. Packets of desiccated coconut were taken from each of the three homes, and each packet gave a positive culture. Samples of the same brand of desiccated coconut were collected from grocery stores and were found to be contaminated. Serologic and biochemical comparisons of these cultures with those isolated from the patients with typhoid corresponded. The brand of desiccated coconut involved is called "Tropic Snow" and is imported by Harrisons Ramsay Pty. Ltd. from Papua, New Guinea. Other brands from Ceylon and Papua have been found to be free from contamination.

Householders in Victoria have been advised by the State Health Minister to burn their supplies of desiccated coconut. The importing firm voluntarily recalled all unsold stocks in wholesale and retail trade channels. In other states, householders have been asked to treat all desiccated coconut as suspect and to boil it before use. All brands of dried coconut are being sampled throughout Australia. So far, no other brands have been found to be infected.

The health department in Papua has been asked to investigate the possible source of infection at the points of manufacture and transport of the desiccated coconut. Wholesale and retail suppliers of this product in Queensland have been ordered to sterilize their stocks of desiccated coconut. Retailers in Victoria have voluntarily destroyed their stocks of the "Tropic Snow" brand. A search of the literature on Typhoid has failed to reveal any evidence of previous epidemics due to desiccated coconut.

BRAZIL

Panamerican Congress of Surgery.—All surgeons of North and South America are being invited to attend the First Panamerican Congress of Surgery, which will be held in Curitiba, state of Parana, Brazil, on Oct. 5-9, 1953. This congress and the second congress of the Brazilian section of the International College of Surgeons will meet jointly under the sponsorship of the government of Parana, as a commemorative event of the first centennial of that state. The official themes are: "Death During Anesthesia," Prof. Max Thorek, Chicago; "Indications and Contraindications of Thoracotomies," Prof. Jorge Taiana, Buenos Aires; and "Surgery of the Biliary Ducts," Dr. Francisco Augusto Pinto, Rio de Janeiro. Other papers of general interest will be presented by speakers from North and South American countries.

Intestinal Obstruction.—In a paper read before the Medical Society of São Paulo, Dr. Luiz Oriente described his research on acute experimental intestinal obstruction and antibiotics, which he performed in the hospital "Julio Pignatari," department of experimental surgery. He employed 11 dogs, separating them in three groups. In the first group, he used

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

penicillin, in the second streptomycin, and in the third a combination of streptomycin plus 30% sodium sulfacetimide. The operations, as well as the reoperations, were performed under aseptic conditions, with intravenous anesthesia. Dr. Oriente compared survival after obstruction had taken place with the results obtained after reoperation, accomplished some hours (10 and 24) after the establishment of occlusion with strangulation. Antibiotics were used only after the operation and were given only by a parenteral route. His conclusions are as follows. The combination of streptomycin plus sodium sulfacetimide gave the best results concerning survival following obstruction and reoperation (resection and anastomosis). These results were confirmed by the clinical course and by examinations of anatomy and pathology. The medicaments greatly increased the safety in acute obstruction, delayed complications, and reduced the mortality rate. They represent potent auxiliary measures in the treatment of acute intestinal obstruction, especially when associated with surgical treatment, but they never should be used to replace or delay surgery.

NORWAY

Indications for Operative Treatment of Uncomplicated Peptic Ulcer.—At a meeting in Oslo last March of the Norwegian Surgical Society the opening address was given by Dr. Olaf Rømcke, who is in charge of the Drammen City Hospital. In collaboration with his colleagues he studied the records of 382 patients who had gastric or duodenal ulcers and who were given routine medical treatment in the Drammen Hospital from the beginning of 1935 to the end of 1937. Three years later 44% of the patients with gastric ulcers and 34% of those with duodenal ulcers were symptom free. After eight years the 44% was reduced to 22% and the 34% to 11%. Patients with a history of symptoms lasting more than five years had a much worse chance of ultimate recovery than patients with a shorter history. For this reason and various others, Rømcke advises operative treatment when symptoms have lasted for more than five years, when a relapse follows medical treatment in hospital, or when the patient cannot remain symptom free with slight dietetic restrictions.

One of the tables in the report showed the percentage of hospital patients selected for operative treatment year by year from 1935 to 1950. In the first year this percentage was only 19, whereas in the year 1949-1950 it was 35. This remarkable trend is largely a sequel to the fall in recent years of the operative mortality and the success with which postoperative hypochylia or achylia is achieved. Quoting the axiom "no acid, no ulcer" Dr. Rømcke would like to see the treatment of peptic ulcer by medical means put on a successful footing by the discovery of a remedy capable of inducing achylia without any troublesome or alarming side-affects.

TURKEY

Syphilis in Afghanistan.—In volume 11, number 2, of *Bursa Klinik*, Prof. Halil Gürün, who spent four years in the department of dermatology and venereal diseases at the medical school in Kabul, Afghanistan, reports on syphilis. In the course of time, foreign armies have traversed and occupied the country so the disease has been there a long time and has become endemic. The people have given the disease different names in different parts of the country. In the north, they call it "Gül-Efshan" probably because of the roseols in the second stage; in the central and southern regions it is named "Satan's disease" because of the terrible effects of the third stage; and in the east near Pakistan, the people say "Iblis," probably a corruption of the word syphilis used by the British physicians in India. In 1951, Professor Gürün made an investigation of the various public schools and found that of 1,713 students from 64 regions 115 (6.65%) had positive serologic reactions. The Kahn, Kolmar, Klein, and venereal disease routine laboratory tests were made at the United Nations International Children's Emergency Fund laboratory in Kabul. These students had all passed the physical examination on admission to the schools. Of 22,419 patients examined at the outpatient clinic in 1951, 2,041 (9.1%) had syphilis, and, of 13,509 patients examined during the first six months of 1952, 1,486 (11%) had syphilis. The World Health Organization team that investigated schools, poorhomes, and prisons arrived at the same percentages.

The majority of 378 patients admitted to Professor Gürün's clinic were in the first and second stages of the disease; 78 patients had primary syphilis; all had spirochete positive reactions; and 72 had positive serologic reactions. Forty-nine patients in the second stage had positive serologic reactions, and, of these, 17 had positive dark field reactions. Of 26 patients with congenital syphilis, 16 had positive serologic reactions. In other departments of the medical school hospital, syphilis is primarily responsible for parenchymatous keratitis, iritis, iridocyclitis, atrophy of the optic nerve, retrobulbar gumma, myelitis, meningitis, leptomeningitis, general paralysis, tabes, and neuritis. The medical department statistics indicate an abundance of visceral syphilis.

The statistics compiled by Dr. Münevver Özdolay, a Turkish physician with many years' experience in Afghanistan, indicate that 12% of the patients she examined had syphilis. The majority of patients in the department of dermatology and venereal diseases of the Mesturat Woman's Hospital show symptoms of syphilis innocentum. Outside of Kabul in the provinces, syphilis resembles an epidemic; patients with third stage lesions predominate. Of 281 patients admitted to the clinic in Aliabad, 127 (45%) had lesions involving destruction of the nose, esophagus, palate, or gums. Destruction of the digestive and respiratory systems often necessitated tracheotomy. In August, 1951, during an investigation of leprosy in Hezaracat, a mountainous, sparsely populated region with scarcely any outside contact, there appeared to be an even higher percentage of syphilitic persons than in Kabul. Investigation in the villages was not possible, but questioning revealed that the disease is widespread and no relief is available. Ignorance, poverty, and lack of medical care and personnel have made the scourge rampant. Outside assistance is urgently needed. There are few pharmacies, and quacks do good business selling pills that contain large amounts of arsenic and mercury and that result in toxemia. Home remedies are also widely used. There is very little foreign currency for the import of foreign pharmaceutical products. Their import is only permitted two agencies, the Ministry of Health and the medical school. The products are stored at the health department, and their release requires many formalities and the signature of the Minister of Health. Some of the products find their way into the black market with the result that lack of a quantity sufficient for effective treatment leads to premature termination of therapy.

Professor Gürün concludes that, if, as he recommended in a letter of Sept. 21, 1951, to Mr. T. Guthe of the World Health Organization, mobile teams with one venereal disease specialist, one serologist, one technician, and equipment were established in Kandihar, Herat, Meymene, Mezarisherif, and Djelalabadand and if the team currently stationed in Kabul were expanded so that native personnel could be trained and health department and health propaganda instituted, it would greatly benefit the Afghan people. There is only one medical school, with 30 students in the first year, that graduates 15 to 20 students each year. Among the faculty are professors from Turkey, Germany, and France. There is one physician to every 40,000 inhabitants. Even if the medical school expands, many years will elapse before public health can come into its own. Currently the allocation for the health department is 3.5% of the general budget; this amount is even inadequate to contend with tuberculosis, malaria, leprosy, parasitic diseases, seasonal epidemics, and salaries for personnel in a country with 12 million inhabitants. The intelligent and industrious Afghan people have preserved their independence in the face of much outside pressure and deserve assistance.

CORRESPONDENCE

CHEST PAIN FROM EXPOSURE TO SOIL DUST

To the Editor:—So-called "dust pneumonia" is a common entity in many areas of the United States where farmers are required to work in air heavily laden with dust particles. It consists of a primary bronchitis and pneumonitis following exposure to dust. In the past, the disease was frequently fatal. It is definitely infectious in character, although mechanical irritation plays a part in the etiology. Chest pain can be caused by exposure to dust. I have seen several patients who have been thoroughly studied for possible accessory factors, and none have been found. The patients were all farmers from the dust bowl area in southeastern Colorado, and each of them had recently begun farming operations that required long and intensive exposure to soil dust. During the period in which these patients were examined, soil dust was not excessive and exposure to dust probably was not any more intense than in any average area in the western states.

An example is a 24-year-old farmer who suffered a gunshot wound of the right apex in 1946; the bullet entered the erector spinae muscles on the right side at the level of the second thoracic vertebra and emerged at the anterior border of the axilla immediately inferior to the lower border of the pectoralis major muscle. This man first noticed vague chest pains several years later. He recalled then that he had been working with very dusty broom corn immediately preceding the onset of these pains. In his own words: "When we worked with the broom corn, the dust fogged up like a storm." He consulted his family physician who told him that he had normal temperature, pulse, respirations, and blood pressure and that there were no signs of disease in the chest. He was given 250 mg. of oxytetracycline (Terramycin) every 6 hours for 12 doses and told to remain indoors. He stated that the pain stopped within 48 hours and that he felt much better. There were no further symptoms until a month later when, once again, he was exposed to dust in the field. He experienced, at that time, moderately severe chest pain indefinitely localized through the right middle lung field. There were occasional severe and lancinating pains. He was again taken to his family physician and was told that the physical examination showed nothing abnormal. On the same day, he was admitted to the regional veterans' hospital where a thorough study was made that included careful neurological and general examination, with emphasis on determination of the possible effect of his old bullet wound on present symptoms. At the conclusion of these studies, the man was told that no cause for his pain had been found. During the next three months, he had repeated episodes of the pain, which became gradually severer. It was still localized, though indefinitely, in the right middle lung field, but it had begun to occur in the left hilar region as well as the right. The pain occasionally seemed to radiate to the right upper arm. Pain was described as dull, with occasional sharp, shooting pains in the same area; it was invariably relieved by staying indoors for a day or two. Physical and roentgenologic examination showed a normal chest. Routine blood and urine studies were normal. Our first thought was that this was a psychoneurotic episode, but careful questioning revealed nothing. We were puzzled by the fact that the pain disappeared during the 48 hours that the patient was in our clinic. The patient himself suggested that the cause might be the dust, and on careful questioning he could recall exposure before each episode of pain and relief within 48 hours of termination of exposure. He purchased a filter type dust mask and has had no further episodes while wearing it. At our request, he worked one day without the mask, and typical pain recurred. He was again examined carefully with the thought of a possible allergy in mind. No signs could be found. He has continued to wear the mask and has had no further symptoms.

Two other cases examined equally thoroughly resulted in similar conclusions and results. In this small series, it would seem that the only possibility is that the inhalation of soil dust produces pain. We believe that an infectious process has been ruled out in all of these cases and that the lesion is unquestionably a mechanical irritation of the larger bronchi. It is possible that anatomic factors causing a more rapid change in direction of the stream of air and dust may be responsible for the consistent appearance of pain on the right. Increasing mechanization in farming probably makes the machine operator subject to inhalation of large amounts of dust. We would recommend a simple filter mask for those so exposed.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Naturopath's Violation of Medical Practice Act By Use of Title "Dr."—The defendant was tried in the municipal court on the charge that he unlawfully advertised and announced himself to be a practitioner of medicine and surgery before he had obtained a certificate from the state medical board as required by law. From a verdict of guilty, he appealed to the court of appeals of Ohio, Franklin County.

The record reveals that the defendant had an office located at 889 East Broad Street, Columbus, Ohio; that hanging over the entrance to the building was a neon sign that read "Dr. Farrand's Naturopathic Clinic." The sign was written in three lines with the word "naturopathic" in the middle and in letters much smaller than the others. Three witnesses testified on behalf of the state concerning treatments received from the defendant on or about the time specified.

It was urged by the defendant that the judgment is contrary to law and he alleged that the record does not reveal that (he) the defendant advertised himself as a practitioner of medicine or any of its branches. The question presented is, therefore, whether the word "naturopathic" as used in the sign prevented any statutory violation that might otherwise have existed. The practice of medicine, said the court, is defined by the General Code, which provides:

"A person shall be regarded as practicing medicine, surgery or midwifery, within the meaning of this chapter who uses the words or letters, 'Dr.' . . . which in any way represents him as engaged in the practice of medicine, surgery or midwifery, in any of its branches. . . .

"The use of any such words, letters or titles in such connection or under such circumstances as to induce the belief that the person who uses them is engaged in the practice of medicine, surgery or midwifery, shall be prima facie evidence of the intent of such person to represent himself as engaged in the practice of medicine, surgery or midwifery."

In connection with the foregoing statute, said the court, the record reveals that the defendant advertised himself as "Dr." The record also reveals that the giving of the massages and treatments for the cure or relief of bodily infirmities or diseases constituted such surrounding circumstances as to induce the belief that he was engaged in the practice of medicine. For these reasons all of the statutory requirements were met in order to sustain a conviction. The use of the word "naturopathic" in the sign does not prevent the act from being a violation. This was clearly pointed out in a prior Ohio case in which the court said:

"The appellant contends that he was practicing naturopathy which is not medicine or any of its branches within the purview of G. C. § 12694. We are not interested in what name or title the appellant gives to his profession, but we are only interested in whether or not what he did constituted the practicing of medicine as defined by G. C. § 1186."

The judgment is, therefore, not contrary to law, said the court of appeals, and the evidence was clearly sufficient to sustain the charge since a prima facie case was established that was never overcome as the defendant offered no evidence in his behalf. Accordingly the judgment of conviction was affirmed. *State v. Farrand, 105 N. E. (2d) 656 (Ohio, 1951).*

Perceptive Deafness Associated with Tetanus Antitoxin.—More than 50% of the neurological complications associated with serum injection have followed the prophylactic administration of tetanus antitoxin; when untreated or alum-precipitated tetanus toxoid is used, reactions of all kinds are markedly reduced. The neuropathological changes following injection of serum are not clearly understood, but they are apparently similar to allergic changes produced elsewhere in the body. Their occurrence cannot be foreseen. Auditory nerve involvement, now reported for the fifth time (twice after therapeutic doses), followed a prophylactic injection of 3,000 units of tetanus antitoxin given to a 23-year-old woman who suffered a laceration of the knee when thrown from a horse. There was no head injury, concussion, or unconsciousness. Generalized giant urticaria, necessitating the use of subcutaneously administered epinephrine for relief, appeared one week after the injection, and on the following day sudden deafness and persistent tinnitus developed. Vertigo was not present at any time. Examination three months later showed that the ear, nose, and throat structures were basically normal; hearing loss amounted to 69% in the right ear and 62% in the left ear, and was complete in both ears at 2,000 cps and above. The diagnosis was bilateral deafness, perceptive type with normal labyrinth, caused by serum reaction following a prophylactic dose of tetanus antitoxin. No improvement was found at follow-up. Attempts at therapy have generally proved ineffectual, but patients with serum sickness showing a tendency toward tinnitus, vertigo, or impairment of hearing should be given immediate treatment to counteract the impending nerve damage. Suggested remedies include epinephrine, the antihistamines, cortisone, and possibly histamine intravenously, but they must be used promptly before the pathological changes are established.

Corticotropin (ACTH) in Lethal Granuloma of Nose and Face.—Lethal granuloma of the nose and face is apparently an allergic lesion closely related to rheumatic fever and certain vascular lesions such as periarteritis nodosa and lupus erythematosus disseminatus. Efforts at treatment were formerly unsuccessful and death from exhaustion or hemorrhage was inevitable, but encouraging results have lately been obtained with cortisone. Seven months' follow-up of a 60-year-old man treated by the authors with corticotropin shows sustained healing of a lethal granuloma involving the nose and face. Complete surgical removal had previously been found impractical and ulceration had followed the breaking down of the operative incision. Penicillin and streptomycin were given intramuscularly in an attempt to control secondary infection and bacitracin and tyrothrycin ointments were applied locally without effect. The patient was then given 25 mg. of corticotropin intramuscularly four times a day and was placed on a low salt diet. Intake-output, weight, and blood pressure records were kept, but no complications of any kind were noted as a result of the treatment. The dosage schedule was changed, after five days, to 25 mg. three times a day for 12 days, and then to 17 mg. three times a day for 8 days. Definite improvement in the lesion was apparent at the end of about two weeks and continued steadily thereafter. Administration of corticotropin was stopped after 25 days, and no further treatment has been needed.

Hereditary Aspects of Heberden's Nodes.—After defining Heberden's nodes, Stecher and associates state that previous studies on the nature of these nodes indicated that the idiopathic form of osteoarthritis of the finger joints is independent of other forms of osteoarthritis, of obesity, or of hypertension; it is related to the menopause, develops only in the presence of normal nerve supply to the hand and fingers, and is inherited as an autosomal sex-influenced trait, being dominant in women and recessive in men. They tested this theory of inheritance on a large family with nine affected persons out of 30 in three generations. Clinical and roentgenological data allow a distinction between idiopathic and traumatic Heberden's nodes. In idiopathic nodes the joint space is narrowed and irregular, and spurs arise from the bones about the terminal joint. In traumatic nodes the joint space is usually normal, the joint surfaces are smooth, and a heavy bony buttress extends dorsally from the proximal end of the distal phalanx. Early cases of idiopathic Heberden's nodes can be recognized radiographically when they are not noted clinically by small islands of bone in the extensor tendons near the distal phalanx. This also occurs as a result of poor expressivity, which explains certain heretofore apparent inconsistencies in the data and makes them thoroughly compatible with the proposed theory of inheritance.

Clinical Evaluation of Dextran in Burns.—A 6% solution of dextran in 0.9% isotonic sodium chloride solution (Macrodex) was given a therapeutic trial in eight patients with thermal burns at the Mayo Clinic. Dextran, as a colloidal agent for combating the potential shock in severe burns, was thought to be equal to human plasma in similar cases. The correction of the existing shock and depletion of blood volume were satisfactory in the authors' patients. No untoward reactions or complications attributable to dextran were observed in these patients. Hemodilution anemia was not a problem. The concentration of proteins decreased after infusion of dextran; this decrease was attributed not only to the effects of hemodilution but also to an active supplanting of the plasma proteins, particularly the albumin fraction. A modification of the Kingsley biuret method has been devised for the determination of proteins and was used satisfactorily in the presence of dextran. Five of the eight patients died of their severe burns, and necropsies were performed in four. They revealed a singular lack of significant pathological changes, with the exception of reversible renal changes in the proximal and distal convoluted tubules. Further investigation of the relationship, if any, between these changes in the convoluted tubules of the kidney and those associated with the syndrome of "lower nephron nephrosis" is desirable. The authors are in accord with Evans and co-workers and others who recommend use of dextran solutions as plasma volume expanders in the treatment of burns that are not extensive. The authors recommend dextran as a useful agent in the early stages of more extensive burns, with the reservation that evidence of renal failure or hemoglobinuric nephrosis should, at present, be considered an indication for use of pooled plasma in preference to dextran. Oral intake of protein supplements is a necessary adjunct of burn therapy and takes on even greater importance with the prolonged use of dextran. Dextran is recommended primarily for use in the early or shock phase of burns and in conjunction with administration of whole blood. The oral route should be utilized whenever possible for administration of protein supplements and as much of the required electrolyte and other noncolloidal solutions as practicable.

Treatment of Hypertension with Hydergine.—Hydergine (containing equal parts of the hydrogenated ergot alkaloids dihydroergocristine, dihydroergocornine and dihydroergokryptine) was given to 200 ambulant patients with hypertension. Half of the patients had mild hypertension with stage 1 and 2 fundus changes and the other half had severe hypertension with stage 3 and 4 fundus changes. Initial treatment was started with from 10 to 20 injections of 1 cc. of Hydergine daily or every other day; then combined treatment with 10 to 30 drops of Hydergine solution or 1 to 2 sublingual tablets three times daily supplemented by biweekly injections was carried out. Of the 100 patients with mild hypertension, 59 responded with lowering of blood pressure and 80 with improvement of subjective symptoms. The corresponding figures in the patients with severe hypertension were 31% and 52% respectively. Of 80 patients with mild hypertension without renal damage, 54 (67.5%) reacted with lowering of blood pressure and 67 (84%) with improvement of subjective symptoms. Of 20 patients with mild hypertension and some renal damage, only 5 (25%) and 13 (65%), respectively, showed improvement. In 54 patients with severe hypertension without renal damage, Hydergine lowered the blood pressure in 27 (50%) and improved subjective symptoms in 39 (72%). Corresponding values for 46 patients with severe hypertension and with renal damage were 10% and 30%. These differences are statistically significant. Experiments with placebos showed that the effect of Hydergine on the blood pressure and subjective symptoms was in most patients not psychogenic. Hydergine was well tolerated. The advantage of ambulant treatment and the necessity of prolonged therapy (not less than three months) is emphasized. Follow-up of patients was not long enough to permit the evaluation of the effect of Hydergine on survival rates.

Paravertebral Block with Aqueous Phenol.—Paravertebral infiltration of the sympathetic chain with 10% phenol in water, either by the lumbar or the thoracic route, was used in 400 patients with circulatory disorders and hyperhidrosis in the extremities. The method was found to be satisfactory for producing lasting sympathetic interruption in the extremities. The substance acts by destruction of the sympathetic ganglion cells. Striking relief of pain and accelerated healing of necrotic areas were obtained in a high proportion of cases of arteriosclerotic ischemia of the foot. About 50% of the patients with intermittent claudication obtained distinct benefit from paravertebral injection of the lumbar chain. Good improvement was obtained in erythrocyanosis and perniosis. If only temporary benefit in acute thrombophlebitis results from a single paravertebral block with *procaine hydrochloride, it is* better to inject aqueous phenol and secure a more lasting sympathetic interruption than to carry out repeated procaine injections. In some cases in which ulcers were present for several years after thrombophlebitis in the legs, injections of phenol were followed by healing within a few weeks. Several cases of mild hyperhidrosis of hands and feet have been successfully treated by paravertebral block with aqueous phenol, improvement having lasted over three years in some of the patients. Although the results of sympathectomy may be more reliable and more lasting, in the many cases that are unsuitable for sympathectomy injection of 10% phenol is an effective substitute. Hyperesthesia in the groin after the lumbar injection, caused by irritation of the genitofemoral nerve, developed in about 10% of the patients. It was seldom troublesome and subsided in about three weeks. The chances of complications are considerably greater with injection of the cervicothoracic portion of the sympathetic chain; intercostal neuritis lasting occasionally up to two months resulted in about 20% of the cases. Complications can be minimized with sound technique and accurate placement of the injection around the sympathetic chain where it is not near important and easily damaged structures.

Selective Lobotomy for Intractable Pain.—Discussing the use of lobotomy in the treatment of intractable pain, Grantham and Spurling say that in 1949 Grantham devised a technique for the selective destruction of certain portions of the prefrontal lobe to avoid resultant intellectual deficits and convulsive seizures. Results similar to those of a complete frontal lobotomy could be achieved by the division of the fibers of the *two medial quadrants of the prefrontal lobe. Electrocoagulation* with a high frequency current is applied by a special needle electrode through bilateral burr holes placed within the hair line 6 or 7 cm. above the glabella and 2½ cm. from the midline. The division was limited to the medial ventral quadrant, and if this was not sufficient, a similar lesion was made in the dorsal ventral quadrant later, thus destroying the association pathways from the medial and orbital surfaces of the prefrontal lobe. At first, only patients in the terminal stages of malignant disease were selected for the operation. These patients were addicted to morphine and no other operative procedure offered any prospect of relief. Later the operation was offered to other patients. To date there have been 71 operations on 51 patients, 18 having a second stage procedure, and two a third stage procedure. Malignant disease was present in 35 and atypical facial neuralgia in 3; the others had causalgia, thalamic syndrome, amebic liver abscess, scleroderma, ununited fracture of the femur, arthritis, complicated lumbar disk disease, and tabes dorsalis. Twenty-four patients lived less than three months after the operation, and in 15 of these pain became tolerable and narcotics were no longer required. Of the 26 patients who survived the operation for up to 43 months (average 15 months), 19 obtained very satisfactory results. Six of the 13 of this group, who are still alive, are carrying on their household duties, 3 men are gainfully employed, and 4 men are semi-invalids because of the primary disease. No patient upon whom this operation was performed for either intractable pain or psychosis (132 patients) developed convulsive phenomena. None of the patients on whom the operation was performed for intractable pain had detectable change in personality. There was one operative death. The authors feel that the *operation should be reserved for those patients with or with-*out drug addiction in whom extreme tension and anxiety are prominent.

***Assessment of Therapy of Burns.**—This statistical evaluation* compares the relative efficacy of the two methods of treating burns and scalds in four institutions in the United States between the years 1944 and 1951. The two methods differed significantly in only two respects: in one whole blood and a buffered saline solution were used to treat peripheral circulatory failure and in the other plasma was employed. In the method in which blood and buffered saline were used to treat the shock, sodium chloride solution was given by mouth for 24 to 60 hours to prevent osmolar dilution (water intoxication) and in the other there was no restriction on water intake. Occlusive dressings were used in all cases. Sulfonamides were given parenterally to a few persons, and penicillin was routinely administered to all patients after 1945. Grafting was performed *in all of the four institutions* as soon as possible. The mortality from thermal injury was the same regardless of the type of therapy employed for injuries covering 15 to 35% and 70 to 100% of the body's surface. The mortality associated with thermal injuries covering 35 to 70% of the body was significantly less in Dallas between 1947 and 1952 and in Kankakee, Ill., than it was in Dallas in 1944 to 1947, and in two hospitals in St. Louis between 1946 and 1951. The reasons for the difference are not apparent. A simple method is presented for the comparative evaluation of burn and scald death rates based on American experience but patterned after the method of Bull and Squire of Glasgow, Scotland. The death rate from thermal injuries covering more than 55% of body surface is still 83%, in spite of the capacity to keep half of those who die alive for five or more days. The death rate among 315 patients who suffered second and third degree burns or scalds covering more than 15% of body surface was 23.8%. The death rate from burns and scalds in four American institutions was practically identical with that observed in Glasgow, Scotland, and Birmingham, England. The treatment of shock is no longer the major problem in burned patients.

Surgical Treatment of Carcinoma of Cervix.—Meigs analyzed the results he obtained with surgical treatment of carcinoma of the cervix in 100 women. The first patient was operated on in 1939 and the last in 1948. The patients all had stage 1 or 2 carcinoma. The series was slow to accumulate, because the author tried to operate on good risk, fairly young, and not too fat patients. The 100 patients were operated on without a death, owing to the use of blood transfusions, antibiotics, sulfonamides, and, above all, the surgeon's judgment as to whether or not he could safely do a radical operation. With increasing experience, nearly all patients with cervical cancer are now considered operable, but surgical treatment of the advanced cases is experimental. Meigs considers here only those who can be operated upon without the removal of bladder or rectum. He feels that roentgen ray and radium irradiation is still the proper treatment for carcinoma of the cervix. A solution of the ureteral, bladder, and rectal problems must be found before surgery can be advocated as a definitive treatment. Of the 100 patients, 75 were living and well five years postoperatively; in fact, many patients lived well beyond five years. Evaluation of the results with regard to the different grades of malignancy revealed that in grade 1 results are very satisfactory, but strangely enough results were better in grade 4 than in grade 3 and in grade 3 better than in grade 2. Of the 25 patients who died, 5 did so because of intercurrent disease and there was no record of recurrence in these 5. In 17 of the fatalities the lymph nodes were involved. Some of the patients had radiation treatment before the operation. A few with fungating growths were deliberately given one-half the usual roentgen ray and radium treatment. More patients who were not treated with radiation are living; more patients who were treated with radiation had lymph node involvement, and there were more fistulas in patients not treated with radiation than in those who were. No cancer was found in the cervix in 21 of the 46 irradiated patients, and only 6 of the 18 still living at the time of writing had received adequate irradiation. Heavy doses of radiation are not necessary to cure localized carcinoma and lymph node lesions will not be destroyed by irradiation. The results of surgical treatment of cancer of the cervix are very satisfactory. The importance of a check of "cured" cases by the pathologist is important, because the cure rate of cancer in situ is nearly 100%, and such cases should not figure in an evaluation of a therapeutic method.

Cincinnati Journal of Medicine

34:197-238 (June) 1953

•Surgical Treatment of Bleeding Esophageal Varices Secondary to Cirrhosis of Liver and Banti's Syndrome. R. R. Linton.—p. 97.

Surgical Treatment of Bleeding Esophageal Varices.—Linton comments on the selection of patients for portacaval shunts and the types of shunts. He reviews results in 83 shunt operations in 79 patients with bleeding esophageal varices. He considers the best method of treatment to be the by-passing of the portal venous blood in patients with bleeding esophageal varices secondary to portal hypertension by the construction of a splenorenal or a direct portacaval shunt. It is important to evaluate the function of the liver in all patients subjected to this type of surgery. In the majority of patients, a splenectomy with an end-to-side splenorenal anastomosis is the preferable procedure, since it carries less risk than a direct portacaval shunt, especially in patients with severely diseased livers. It also carries less risk in patients with the so-called Banti's syndrome (congestive splenomegaly), since in them the exposure of the portal vein is frequently impossible due to the cavernomatous change in the gastrohepatic ligament. Portacaval shunts should be reserved for the treatment of bleeding esophageal varices; they are not to be recommended for the treatment of ascites alone. A surgeon should not do a splenectomy alone unless he is prepared to do a splenorenal anastomosis at the same operation, since this may be the only opportunity to construct a satisfactory shunt.

Studies of Vasospasm.—Use of glyceryl trinitrate in a test for vasospasm was studied in 96 persons. Nineteen had normal vasomotor tone, 29 had increased vasomotor tone as a result of Raynaud's disease and other syndromes with vasospasm as a prominent feature, and 48 had occlusive arterial disease. Observations were made before and after sublingual administration of 0.4 mg. of the drug on the character of the peripheral pulses, pulse rate, blood pressure, oscillometric readings in the feet and legs (and, when appropriate, at the wrist), and the color, temperature, and moisture of the hands and feet. Thirteen of the group were also tested in a constant temperature room where skin temperature studies and arterial pulse tracings were made. The results observed permit the following conclusions: Sublingual administration of glyceryl trinitrate aids greatly in the interpretation of the weak or peripheral pulse. It releases vasomotor tone of peripheral arteries, and the pulse that is weak or absent as a result of vascular spasm becomes bounding in character. Vessels totally occluded by organic disease remain impalpable. Vessels organically diseased and partially occluded increase their pulsation only to the degree of tone permitted by the pathological changes. Oscillometric readings are increased in proportion to the release of vasomotor tone. In most of the patients responding with an increase in pulsation, no increase in skin temperature or change in color or moisture of the skin occurred. Occasionally such changes were observed in digits in which the vessels had been in very severe spasm as in an acute Raynaud's syndrome. In no patient was there any serious discomfort. The glyceryl trinitrate test is simple to carry out and has practical clinical importance as a diagnostic procedure. It should not be used on patients in whom the maintenance of vasomotor tone is important, as in shock, febrile conditions, and debilitation. Recent myocardial infarction, anemia, and increased intraocular and intracranial pressure are additional contraindications to this test.

Anticoagulants in Myocardial Infarction.—The clinical records of 1,350 patients with coronary thrombosis and myocardial infarction who were hospitalized in several hospitals from 1941 to 1950 were studied with respect to (1) correlation of the patient's condition on admission with the mortality rate, utilizing a quantitative method for determining degrees of illness; (2) the relationship of age to mortality rate; (3) comparison of certain items in this group with similar items in the study of the committee for the evaluation of anticoagulants in the treatment of myocardial infarction of the American Heart Association; (4) the effect of anticoagulant therapy on the mortality rate in several hospitals during one year as compared with mortality rates before anticoagulants were used. The published reports of reduced incidence of thromboembolism in treated groups as compared with control groups have not conclusively demonstrated that the decrease is wholly attributable to anticoagulant therapy rather than to such other factors as erroneous diagnosis, unconscious bias of the medical examiner, and deviations from the stringent requirements of truly controlled studies. Unless additional evidence to the contrary is presented, there would appear to be little reason to prescribe anticoagulants routinely in persons who are not severely ill because of the expense, inconvenience, dangers, and difficulty of maintaining constantly "effective" prothrombin blood levels. In more seriously ill patients, the theoretical advantages of anticoagulant therapy justify this treatment even though there may be some question as to whether its value has been demonstrated.

Effect of Valsalva Maneuver on the Circulation.—A study was made of the circulatory responses to the Valsalva maneuver by 10 normal persons and 51 patients. Of the patients, 22 had mitral stenosis, 3 pericarditis, 3 pulmonary vascular disease, 5 kyphoscoliosis, 3 organic heart disease without congestive failure, 6 organic heart disease with a history of congestive failure, and 9 congenital heart disease. The normal response following sustained straining, as in the Valsalva maneuver, is a rise in systemic arterial pressure and a reflex slowing of the heart rate. Normally there is a small overshoot in pulmonary artery pressure. This normal response was abolished in all three patients with pericarditis, in several patients with organic heart disease in whom congestive heart failure had been conspicuous in the past or was present at the time of testing, in some of the patients with pulmonary vascular disease (including kyphoscoliosis), and in some types of congenital heart disease. Pulmonary artery pressure did not rise after straining when there had been failure of the right ventricle. By observing the development of bradycardia electrocardiographically following straining, the clinician has a simple and useful tool for appraising the integrity of the cardiovascular system, since the presence of bradycardia suggests that overshoot in the systemic arterial pressure occurs. The absence of bradycardia when the autonomous system is intact suggests that an overshoot of systemic arterial pressure does not occur. The Valsalva maneuver, when performed under electrocardiographic control, is a simple, dynamic stress test of the circulation.

Occupational Potentialities of the Older Cardiac Patient.—The report concerns persons who are 55 years of age or over at the time heart disease develops. Records of 580 patients revealed that many patients with cardiac defects in the sixth and seventh decades of life can and do work successfully. Although continued employment does not have any adverse effect on the course of heart disease, the employment of the cardiac patient over 55 is less successful than that of the younger person with heart disease. The cardiac capacity of patients whose heart disease develops after 55 years of age is usually initially diminished to a greater extent than that of younger cardiac patients. Selective job placement presents greater problems in elderly persons. A study of the employment needs of 33 patients over 55 years of age with degenerative heart disease showed that 20 were working and 6 more were considered employable; only 7 were unable to work because of cardiac disability. This study and statistical analyses indicate that counseling and placement agencies should interview all cardiac patients whom the physician considers employable. Physicians should supplement the functional and therapeutic classifications with specific recommendations concerning hours per day or per week, and amounts of carrying, lifting, walking, and traveling a patient can do. Through selective placement, and with a reasonable amount of medical supervision, a considerable proportion of cardiac patients in the sixth and seventh decades can remain in useful employment.

Peritoneal Dialysis in Toxic Conditions.—Peritoneal dialysis is an *effective method of* rinsing out toxins and removing nonprotein *nitrogen from* the body. It can be used as a substitute for kidney function for 20 days or more. It is contraindicated when inflammatory processes are present in the vicinity of the peritoneum and when the patient's general *condition is poor and the efficiency of the heart and vessels is reduced to the minimum. It was used successfully in* 5 of 17 "hopeless" *cases of renal injury;* death in the other *12 cases resulted from irreversible lesions* in the kidney or *uncontrollable complications.* Indications for peritoneal dialysis in the presence of anuria are the sudden appearance of uremia, *either as a symptom* of intoxication or as a complication *of incompatible blood* transfusion or various lesions (lower *nephron nephrosis).* Dialysis is also valuable in uremia with *extreme oliguria* caused by a reversible renal lesion, and in cases of soporific intoxication it may prove lifesaving. Stoppage of the outflow can be avoided or remedied by the use of two outflow catheters. Edema, which occurs on about the fifth day of dialysis, requires the intravenous administration of concentrated dextrose solution; pulmonary edema, encountered in three cases, occurred only in patients with inadequate *circulation.* An excessive reduction of albumin in the blood, which sometimes appears on the sixth or seventh day, can be corrected with blood transfusions.

Treatment of *Myasthenia* by Carotid Sinus Denervation.—*Follow-up* of 10 patients with typical bulbospinal myasthenia and 3 with ophthalmoplegic myasthenia subjected to carotid sinus denervation showed *one patient* cured, 7 improved (3 considerably), and 5 not benefited. A patient with residual symptoms, however slight, cannot be considered completely *cured,* because such symptoms *may be indicative* of a latent condition with *evolutionary potentialities.* No residual symp*toms* could be detected on neurological examination of the *patient considered cured.* Within six months after the *inter*vention, which was bilateral, he was able to discontinue ingestion of prostigmine, and one month later he resumed an *active life* as an army officer. Residual myasthenia, though compatible with a normal or nearly normal life either without prostigmine therapy or with small doses for maintenance, usually deprives the patient of the capacity for great *muscular* effort, and severe failure may occur if overwork is suddenly imposed on the weakened bulbar apparatus. Even *mild* bronchopulmonary infections in myasthenic patients should receive careful attention. Carotid sinus denervation *is never an* emergency procedure and should not be attempted in all *cases.* It is indicated chiefly when a patient with generalized myasthenia has persistent bulbar disturbances *in spite of rest* and doses of prostigmine amounting to more than 10 tablets daily. Insufficient regression after stabilization with prostigmine and frequent acute attacks are also indications for the procedure. Denervation may be associated with operative removal of an *intrathoracic* or *thymic tumor,* either as a preparatory step to lessen the operative risks or later if the tumor *proves malignant* or the myasthenia remains unchanged after temporary regression. Denervation may be *unilateral* or *bilateral,* with a *variable interval* between the two interventions. Local anesthesia should be used exclusively, and a mechanical respiratory apparatus should be ready for use during the procedure if needed. The optimal dose of prostigmine is determined by preoperative study of the patient and is routinely increased by one-third on the day of the operation and for three days thereafter, even in the absence of symptoms.

Tumors in Dogs Fed *o*-Aminoazotoluene or *p*-Dimethylaminoazobenzene.—While *o*-aminoazotoluene and *p*-dimethylaminoazobenzene were known to produce tumors in rats and mice, a carcinogenic action in dogs had not been previously reported. Of five dogs fed 5 mg. per kilogram of body weight per day of *o*-aminoazotoluene, one died without tumor after four months; the others were fed for 30 to 62 months, and all four of these had tumors. Two had tumors in the urinary bladder and two had tumors in the liver and gallbladder. At a dosage level of 20 mg. per kilogram per day of the same compound, all of five dogs died within eight weeks, principally from liver damage, without tumor. Of 10 dogs fed 20 mg. per kilogram per day of *p*-dimethylaminoazobenzene, eight died within 16 months, without tumor. The remaining two showed bladder tumors after 38 and 48 months, respectively. At a dosage of 5 mg. per kilogram per day of the same compound, none of six dogs fed for 63 months and none of three that died earlier had tumors. The two dyes were among nine different aromatic amines (studied because they were possible food contaminants) and food dyes whose chronic toxicity was being investigated.

Cerebral Injuries from Atomic Bombardment.—The 37 brains studied by Uchimura and Shiraki were from victims of the atomic bomb explosions at Hiroshima and Nagasaki. The patients died from 19 to 64 days after the explosion. The group included none who either died very early or after a protracted course of illness. Two-thirds of the patients were less than 30 years of age. Severe changes were found in 32 of the 37 cases. On the basis of the pathological changes, two groups could be distinguished: the first showed changes due to circulatory disturbances comparable to those which have been described as the result of excessive doses of radium and roentgen radiation but with certain deviations from the known forms of radiation damage. The second group showed severe selective changes and even destruction of nerve cells.

Fatal Complications from Use of Iodopyracet for Angiography.—Four cases are reported in which the use of iodopyracet (Diodrast) for angiography proved fatal. There were manifestations of severe damage to the central nervous system immediately after the iodopyracet had been injected. Death occurred in 40 hours, 3 days, 10 days, and 10 days respectively. In the one case in which thyroid angiography had been performed, the iodopyracet reached the brain by way of the vertebral artery. In the other three cases cerebral angiography was performed; postmortem examination revealed an old calcified cortical scar in one, a berry aneurysm of the circle of Willis and old cerebral infarction in another, while in the third no cause was found for the signs and symptoms occurring prior to angiography. Infarction of the brain was observed in all four cases. There was evidence to indicate that the infarction was the consequence of vascular changes chemically induced by the iodopyracet.

*Experiences with Hypophysectomy in Man. R. Luft and H. Olivecrona. —p. 301.

Hypophysectomy in Man.—The authors report on 26 hypophysectomies. Three of the patients had Cushing's syndrome, 7 malignant hypertension, 4 diabetes mellitus, and 12 malignant tumors. Coagulation of the pituitary was done in two of the three patients with Cushing's syndrome and partial resection of the gland in one. Rapid improvement resulted from coagulation in one patient, who was well 15 months after the operation and had even become pregnant. The two other patients died within the first three postoperative days. Results of hypophysectomy in the patients with malignant hypertension were disappointing; five patients died of an extradural clot, subdural hematoma, or acute cerebral edema within the first few postoperative days. The two patients who stood the operation best died of uremia two and five months after the operation. One of the four patients with diabetes mellitus made an uneventful recovery and now requires 12 units of insulin instead of the 80 units required before the operation. The other three patients died within the first few postoperative days. Acute cerebral edema after hypophysectomy appears to occur only in patients with diabetes mellitus, Cushing's syndrome, and malignant hypertension. This reaction did not occur, at least not in a violent form, after hypophysectomy in patients with malignant tumors. Of these 12 patients, 1 had carcinoma of the prostate gland, 1 malignant chorionepithelioma, 1 hypernephroma, and 9 carcinoma of the breast. Difficulties of urination and defecation disappeared for three months after incomplete hypophysectomy in the patient with cancer of the prostate gland. Relief of pain lasted until his death, which occurred four months after the operation. The patient with hypernephroma tolerated the hypophysectomy well, but the disease was progressing three months after the operation. The patient with malignant chorionepithelioma was temporarily improved for four months after the operation, but died six months after the operation. In the nine patients with carcinoma of the breast the disease was advanced, with large recurrences after previous mastectomies and with pulmonary and other metastatic lesions. Follow-up after hypophysectomy has been too short to permit any conclusion concerning the effect of the operation on the cancer. The authors' experience indicates that hypophysectomy is well tolerated, that reactions similar to those observed in endocrine disorders and malignant hypertension do not occur, and that unless hypophysectomy is complete only a temporary effect of short duration is to be expected. When the hypophysectomy is complete, as it was in a 49-year-old woman, a remarkable regression of the carcinoma may occur, although the authors do not know how long this improvement is going to last. They believe that carcinomas of the breast and possibly also of the prostate, as well as chorionic epitheliomas in a stage when other methods of treatment are no longer effective, offer a promising field for hypophysectomy.

Peritoneal Dialysis in Toxic Conditions.—Peritoneal dialysis is an effective method of rinsing out toxins and removing nonprotein nitrogen from the body. It can be used as a substitute for kidney function for 20 days or more. It is contraindicated when inflammatory processes are present in the vicinity of the peritoneum and when the patient's general condition is poor and the efficiency of the heart and vessels is reduced to the minimum. It was used successfully in 5 of 17 "hopeless" cases of renal injury; death in the other 12 cases resulted from irreversible lesions in the kidney or uncontrollable complications. Indications for peritoneal dialysis in the presence of anuria are the sudden appearance of uremia, either as a symptom of intoxication or as a complication of incompatible blood transfusion or various lesions (lower nephron nephrosis). Dialysis is also valuable in uremia with extreme oliguria caused by a reversible renal lesion, and in cases of soporific intoxication it may prove lifesaving. Stoppage of the outflow can be avoided or remedied by the use of two outflow catheters. Edema, which occurs on about the fifth day of dialysis, requires the intravenous administration of concentrated dextrose solution; pulmonary edema, encountered in three cases, occurred only in patients with inadequate circulation. An excessive reduction of albumin in the blood, which sometimes appears on the sixth or seventh day, can be corrected with blood transfusions.

Treatment of Myasthenia by Carotid Sinus Denervation.—Follow-up of 10 patients with typical bulbospinal myasthenia and 3 with ophthalmoplegic myasthenia subjected to carotid sinus denervation showed one patient cured, 7 improved (3 considerably), and 5 not benefited. A patient with residual symptoms, however slight, cannot be considered completely cured, because such symptoms may be indicative of a latent condition with evolutionary potentialities. No residual symptoms could be detected on neurological examination of the patient considered cured. Within six months after the intervention, which was bilateral, he was able to discontinue ingestion of prostigmine, and one month later he resumed an active life as an army officer. Residual myasthenia, though compatible with a normal or nearly normal life either without prostigmine therapy or with small doses for maintenance, usually deprives the patient of the capacity for great muscular effort, and severe failure may occur if overwork is suddenly imposed on the weakened bulbar apparatus. Even mild bronchopulmonary infections in myasthenic patients should receive careful attention. Carotid sinus denervation is never an emergency procedure and should not be attempted in all cases. It is indicated chiefly when a patient with generalized myasthenia has persistent bulbar disturbances in spite of rest and doses of prostigmine amounting to more than 10 tablets daily. Insufficient regression after stabilization with prostigmine and frequent acute attacks are also indications for the procedure. Denervation may be associated with operative removal of an intrathoracic or thymic tumor, either as a preparatory step to lessen the operative risks or later if the tumor proves malignant or the myasthenia remains unchanged after temporary regression. Denervation may be unilateral or bilateral, with a variable interval between the two interventions. Local anesthesia should be used exclusively, and a mechanical respiratory apparatus should be ready for use during the procedure if needed. The optimal dose of prostigmine is determined by preoperative study of the patient and is routinely increased by one-third on the day of the operation and for three days thereafter, even in the absence of symptoms.

Tumors in Dogs Fed *o*-Aminoazotoluene or *p*-Dimethylaminoazobenzene.—While *o*-aminoazotoluene and *p*-dimethylaminoazobenzene were known to produce tumors in rats and mice, a carcinogenic action in dogs had not been previously reported. Of five dogs fed 5 mg. per kilogram of body weight per day of *o*-aminoazotoluene, one died without tumor after four months; the others were fed for 30 to 62 months, and all four of these had tumors. Two had tumors in the urinary bladder and two had tumors in the liver and gallbladder. At a dosage level of 20 mg. per kilogram per day of the same compound, all of five dogs died within eight weeks, principally from liver damage, without tumor. Of 10 dogs fed 20 mg. per kilogram per day of *p*-dimethylaminoazobenzene, eight died within 16 months, without tumor. The remaining two showed bladder tumors after 38 and 48 months, respectively. At a dosage of 5 mg. per kilogram per day of the same compound, none of six dogs fed for 63 months and none of three that died earlier had tumors. The two dyes were among nine different aromatic amines (studied because they were possible food contaminants) and food dyes whose chronic toxicity was being investigated.

Cerebral Injuries from Atomic Bombardment.—The 37 brains studied by Uchimura and Shiraki were from victims of the atomic bomb explosions at Hiroshima and Nagasaki. The patients died from 19 to 64 days after the explosion. The group included none who either died very early or after a protracted course of illness. Two-thirds of the patients were less than 30 years of age. Severe changes were found in 32 of the 37 cases. On the basis of the pathological changes, two groups could be distinguished: the first showed changes due to circulatory disturbances comparable to those which have been described as the result of excessive doses of radium and roentgen radiation but with certain deviations from the known forms of radiation damage. The second group showed severe selective changes and even destruction of nerve cells.

Fatal Complications from Use of Iodopyracet for Angiography.—Four cases are reported in which the use of iodopyracet (Diodrast) for angiography proved fatal. There were manifestations of severe damage to the central nervous system immediately after the iodopyracet had been injected. Death occurred in 40 hours, 3 days, 10 days, and 10 days respectively. In the one case in which thyroid angiography had been performed, the iodopyracet reached the brain by way of the vertebral artery. In the other three cases cerebral angiography was performed; postmortem examination revealed an old calcified cortical scar in one, a berry aneurysm of the circle of Willis and old cerebral infarction in another, while in the third no cause was found for the signs and symptoms occurring prior to angiography. Infarction of the brain was observed in all four cases. There was evidence to indicate that the infarction was the consequence of vascular changes chemically induced by the iodopyracet.

*Experiences with Hypophysectomy in Man. R. Luft and H. Olivecrona.—p. 301.

Hypophysectomy in Man.—The authors report on 26 hypophysectomies. Three of the patients had Cushing's syndrome, 7 malignant hypertension, 4 diabetes mellitus, and 12 malignant tumors. Coagulation of the pituitary was done in two of the three patients with Cushing's syndrome and partial resection of the gland in one. Rapid improvement resulted from coagulation in one patient, who was well 15 months after the operation and had even become pregnant. The two other patients died within the first three postoperative days. Results of hypophysectomy in the patients with malignant hypertension were disappointing; five patients died of an extradural clot, subdural hematoma, or acute cerebral edema within the first few postoperative days. The two patients who stood the operation best died of uremia two and five months after the operation. One of the four patients with diabetes mellitus made an uneventful recovery and now requires 12 units of insulin instead of the 80 units required before the operation. The other three patients died within the first few postoperative days. Acute cerebral edema after hypophysectomy appears to occur only in patients with diabetes mellitus, Cushing's syndrome, and malignant hypertension. This reaction did not occur, at least not in a violent form, after hypophysectomy in patients with malignant tumors. Of these 12 patients, 1 had carcinoma of the prostate gland, 1 malignant chorionepithelioma, 1 hypernephroma, and 9 carcinoma of the breast. Difficulties of urination and defecation disappeared for three months after incomplete hypophysectomy in the patient with cancer of the prostate gland. Relief of pain lasted until his death, which occurred four months after the operation. The patient with hypernephroma tolerated the hypophysectomy well, but the disease was progressing three months after the operation. The patient with malignant chorionepithelioma was temporarily improved for four months after the operation, but died six months after the operation. In the nine patients with carcinoma of the breast the disease was advanced, with large recurrences after previous mastectomies and with pulmonary and other metastatic lesions. Follow-up after hypophysectomy has been too short to permit any conclusion concerning the effect of the operation on the cancer. The authors' experience indicates that hypophysectomy is well tolerated, that reactions similar to those observed in endocrine disorders and malignant hypertension do not occur, and that unless hypophysectomy is complete only a temporary effect of short duration is to be expected. When the hypophysectomy is complete, as it was in a 49-year-old woman, a remarkable regression of the carcinoma may occur, although the authors do not know how long this improvement is going to last. They believe that carcinomas of the breast and possibly also of the prostate, as well as chorionic epitheliomas in a stage when other methods of treatment are no longer effective, offer a promising field for hypophysectomy.

Chemotherapy in Renal Tuberculosis.—A total of 458 patients with genitourinary tuberculosis have been treated with chemotherapy alone by the research group of the Veterans Administration. The objective was to determine the optimum long-range dosage plan for streptomycin and other new antituberculosis drugs. This study has now been in progress for five years. Streptomycin and *p*-aminosalicylic acid were effective in slowing the progress of the disease, even when the urine could not be sterilized. Inoperable, bilateral renal tuberculosis was treated with from one to three years of intermittent combined therapy (12 gm. of *p*-aminosalicylic acid daily, plus 1 gm. of streptomycin two times per week). Unilateral, destructive renal tuberculosis, with visible x-ray changes and with the contralateral kidney showing no pus cells and no tubercle bacilli in the ureteral urine, was treated by nephrectomy. In occasional cases partial nephrectomy proved practical when combined with chemotherapy. Chemotherapy was continued after operations until pyuria ceased. Isoniazid improves the bladder lesions of renal tuberculosis, and the urine culture becomes negative in some patients. Limitations of isoniazid appear to be the same as those of streptomycin if the drug is used alone. Drug resistance may develop after from four to eight weeks, and the urine from large necrotic kidney lesions cannot always be sterilized. In patients with nitrogen retention isoniazid accumulates in the blood, and blood levels should be ascertained in order to prevent convulsions. Hyper-reflexia is not a true index to the blood level and cannot be depended on as a warning sign of impending toxicity. When blood levels can be determined, this drug can be an important addition to the treatment of even uremic patients with massive kidney lesions. Drug resistance was the most important limiting factor in the effectiveness of streptomycin, *p*-aminosalicylic acid, and isoniazid. Since the mode of action of all three drugs appears to be different, it is reasonable to assume that a combination may greatly increase their effectiveness and further defer the development of drug resistance. Five years of follow-up studies appeared to justify the conclusion that modern chemotherapy can at least modify the lethal course of renal tuberculosis.

Total Prostatectomy in Carcinoma of Prostate.—Castration and the estrogens have had a profound effect upon cancer of the prostate but there is little evidence that these measures are curative. A fair comparison between results of estrogen therapy and radical surgery is difficult, because antiandrogenic therapy has been applied to many stages of cancer, whereas total prostatectomy has been used only in cases in which the cancer was localized to small areas within the gland or the lesion appeared to be confined to the capsule of the gland. One hundred total prostatectomies performed at the Massachusetts General Hospital during the past 20 years for suspected cancer were reviewed. In spite of clinical evidence that cancer was present, no malignant disease existed in 21 of these patients. It should be recognized that early cancer of the prostate produces no symptoms. Symptoms present when the cancer is in an early stage usually are due to associated benign hypertrophy. Rectal examination gave correct diagnostic information in 73 of the 100 cases; in the remaining 27 it was misleading. Results of cytological examination of expressed prostatic secretion were confirmed in only about 40% of the cases. The most that can be said for needle biopsy is that when the specimen contains malignant cells, the patient does have cancer. Perineal biopsy and examination of frozen sections proved the most dependable and accurate diagnostic procedure. The operative technique of Young was generally used. The operative mortality was 5%. Of the 41 patients who underwent total prostatectomy before 1949, 26, or nearly two-thirds, were clinically free of disease at the end of three years. Fifteen of the 29 patients were alive and clinically free of disease five years after total prostatectomy. One was living with possible recurrence. Ten had died of cancer. Only one of the 15 five year survivors had subsequently died of cancer at the time of writing, and he died six years after operation. Total prostatectomy is gaining in favor. At the author's clinic nearly four times as many of these operations have been performed during the past 10 years as during the previous decade. He feels that the functional results justify the procedure.

Erythroplasia of Queyrat.—According to Merricks and Cottrell, Queyrat's erythroplasia usually involves the glans penis, but it may involve the coronal sulcus and the prepuce. It is of a chronic nature and is characterized by the persistence of slightly sensitive red plaques lightly infiltrating the mucous membranes. The majority of authors consider the cause unknown, although irritation, trauma with or without scar formation, inflammation, and syphilis have been postulated as predisposing factors. The disease is comparatively rare, the world literature reporting a total of 260 cases, to which these authors add a new case. A 79-year-old man complained of gradual tightening of the foreskin for the previous three years. During this time two paraphimotic episodes had occurred. Circumcision had been refused twice. At examination the foreskin could not be retracted and was becoming increasingly tender. Circumcision by the dorsal slit, lateral flap method was performed. Dense adhesions were encountered in freeing the prepuce, revealing an ulcerated glans. The glans was slow to heal. After 22 days the patient was discharged. During the next six months various ointments and chemicals failed to bring about complete healing. A biopsy taken at this time revealed Queyrat's erythroplasia and suggested malignant degeneration. Most authors consider this lesion precancerous or malignant, since degeneration into malignant epitheliomas occurs in 20 to 40% of the cases. In the case reported here the penis was amputated five months after the circumcision. The surgical specimen indicated a transitional cell carcinoma developing from Queyrat's erythroplasia. Amputation is the only adequate treatment for an advanced lesion.

Case of Queyrat's Erythroplasia.—A 39-year-old man had a small lesion on the left dorsal surface of the mucosal aspect of the prepuce for 10 years that had resisted local therapy. The lesion consisted of an oval, slightly elevated, orange-brown area 1.5 cm. long, with tiny, hard smooth papillary projections and multiple longitudinal fissures that burned and opened from time to time. The patient was circumcised well outside the pathological area, insuring eradication. The postoperative course was uneventful. The author stresses that Queyrat's erythroplasia is a serious disease and that therapy must be governed accordingly.

Brucellosis in Man.—The occurrence of Brucella abortus (brucellosis) is reported in 35 men between the ages of 21 and 59 years. There were 13 farmers who owned cows affected with Bang's disease, 15 packing plant employees, 1 veterinarian, and 6 who had no direct animal contacts, but 5 of these consumed unpasteurized milk or cheese and one often repaired radios covered with manure. Symptoms of the disease were multiple and varied. Clear-cut symptoms relating to the digestive or respiratory system were usually lacking. Physical abnormalities such as fever, lymphadenopathy, weight loss, and enlargement of the spleen and liver were few and inconclusive. Br. abortus was isolated from the blood of every patient. All had serum agglutinins ranging in titer from 1:160 to 1:5,120. The diagnosis rested principally on the epidemiological and clinical history, the agglutination test, and the blood culture. Only the last was decisive. Aureomycin in doses of 2 gm. daily for 7 to 21 days proved to be the most satisfactory therapeutic agent. There seemed to be no advantage in adding streptomycin or dihydrostreptomycin. Corticotropin (ACTH) controlled fever and toxicity but not bacteremia. Corticotropin may be a useful adjunct to chemotherapy in critically ill patients. Since human brucellosis can nearly always be traced to an animal source, control of the human disease depends primarily on the extermination of the animal reservoir. Pasteurization of milk and other dairy products is helpful but will not eliminate human brucellosis.

Antibiotic Therapy in Bacterial Endocarditis.—Two men and one woman with subacute bacterial endocarditis and histories of previous severe reactions to penicillin G were successfully treated with penicillin O in doses of 600,000 to 3,000,000 units per day. All three patients had mild sensitivity reactions to penicillin O, but the erythematous maculopapular rash, exfoliative reaction, and urticaria were not severe enough to warrant cessation of administration of this form of penicillin. Penicillin G was administered subsequently in gradually increasing doses, up to 10 million units per day in two of the authors' three patients, without any untoward reactions. Antihistaminic drugs were used in all three patients in an attempt to minimize the extent of reactions. The considerably milder nature of the reactions with penicillin O indicates that the latter form of penicillin was of benefit in the treatment of these patients. While it is evident that penicillin O is not the final answer to the problem of sensitivity to penicillin, it offers one more approach to the treatment of patients with subacute bacterial endocarditis who are sensitive to penicillin G and in whom use of penicillin is indicated.

Pancreaticoduodenal Cancer.—The term pancreaticoduodenal cancer includes tumors of the head of the pancreas, the ampulla of Vater, the common bile duct, and the duodenum. All these cancers have in common the fact that a relatively standardized operation, pancreaticoduodenectomy, has been employed in their removal. This paper presents the results of radical resection of pancreaticoduodenal carcinoma. The authors compare the results of both curative and palliative surgical treatment in the 183 patients treated during the last decade (1941-1950) with the clinical course of the same types of carcinoma in 132 patients treated during the preceding decade (1931-1940). In the first decade only palliative surgery was employed regardless of the size of the tumor, duration of symptoms, or condition of the patient. The conclusion drawn from the comparison of these two groups is that little or nothing has been accomplished by pancreaticoduodenectomy if the results are viewed from the standpoint of over-all salvage. In some cases radical resection has been of palliative value and, in a still smaller group, has achieved five year survival and possibly permanent eradication of the disease. Therefore, even on the basis of these discouraging statistics, one should not advocate abandonment of pancreaticoduodenectomy, even in cancer of the head of the pancreas, which has the most unfavorable prognosis. Cancer of the duodenum seems to carry a relatively more favorable prognosis. The authors feel that recently described methods of resection of the portal vein and accompanying lymphatics may improve the results of radical surgical removal of these tumors.

Skim Milk Powders and Experimental Caries.—Previous studies on experimental rat caries suggested the possibility of a relation between heat-processed cereal foods and the etiology of dental caries. Continuing this type of study, the cariogenic role of heat-processed skim milk powders was investigated. Diets containing 35% of commercial skim milk powders prepared by the usual spray and roller processing and also given a subsequent heat treatment prior to feeding have been identified with the production of a specific type of surface caries in white rats. The extent and severity of the caries was significantly and consistently increased by heat treatment of these commercial skim milk powders. The results suggest that a cariogenic effect may be produced by heat treatment of dry skim milk powders. According to present evidence, this cariogenic effect has not been identified with the nutritive growth failures usually associated with heat or storage deterioration of milk proteins.

Effects of Mineral Deficiencies on Amino Acid Utilization.—Results of studies presented in this paper point to the critical role of potassium in amino acid utilization following protein depletion. Rats depleted only of protein failed completely, even when offered a complete source of amino acids, if at the same time potassium was withheld. If phosphorus was withheld during the repletion period, the rate of recovery was slower, but complete failure and deaths did not result as with potassium deprivation. Deprivation of sodium, calcium, or magnesium did not appear to have immediate limiting effects on the appetite of protein-depleted rats for a complete amino acid source or on their ability to recover lost weight.

Treatment of Myasthenia Gravis.—Since 1948, a pyridine homologue of neostigmine (Pyridostigmine), was given a therapeutic trial in 23 patients with myasthenia gravis associated with pseudoparalysis. Results of animal experiments, which have not yet been published, showed that Pyridostigmine is five times less toxic than neostigmine, while the effect of the new preparation on the isolated intestine in vitro and in situ is only half that of neostigmine. Most of the author's patients had been treated previously with neostigmine, but there was only little improvement and the drug was not well tolerated. Result of treatment with Pyridostigmine showed that the effect of the drug on the muscles was prolonged, so that single doses of the drug could be given at longer intervals. The improvement of the functional capacity of the muscles was definitely superior to that obtained with neostigmine. The muscles of the trunk and of the extremities were most favorably affected by Pyridostigmine; the drug was least effective with respect to the external muscles of the eye. Undesirable side-effects were rare and mild. It was possible to administer large doses of the drug for prolonged periods. The dose required varied with the individual patient; while in some patients 4 tablets daily were sufficient, 12 tablets daily were required in other patients. Results with Pyridostigmine were definitely superior to those obtained with neostigmine as far as improvement of symptoms was concerned. A cure of the disease, however, could not be accomplished with Pyridostigmine.

Indications, Technique, and Prognosis in Arthroplasty of Hip Joint.—In Westerborn's opinion the results of arthroplasty of the hip joint by the Smith-Petersen technique justify the procedure, and the same is probably true of Judet's operation. In Sahlgren Hospital arthroplasty was performed in about 200 cases from 1947 to 1951. Follow-up examination revealed a high percentage of good late results of the Smith-Petersen operation; Judet's method with an acrylic substance has been in use only the last two years. Patients treated by Judet's operation have on the whole been less affected by the operation, and the immediate results have been satisfactory in most cases. After Smith-Petersen's cup plasty a number of patients have been able to resume occupations involving heavy physical work. Light work is advised for the first two years if possible. Reschooling for unskilled workers not too old to learn to do lighter work might be advisable. The main indications for arthroplasty of the hip joint are osteoarthritis, deforming arthritis of different origins, subluxations, and sequelae of loosening of epiphysis, Perthes disease, pseudoarthrosis, and necrosis of the head of the femur. Special indications for Judet's method include osteoarthritis with marked cystic degeneration of the head, necrosis of the head of the femur, pseudoarthroses, and certain fractures of the neck of the femur. Satisfactory results depend on thorough and careful technique and careful selection of patients; prolonged aftercare and training are fundamental, and the patient's active cooperation is essential. The results are mainly endangered by formation of new bone. The best results are attained in young and middle-aged patients who are not greatly overweight. Heavy and indolent persons are poorly adapted for the intervention. Evaluation, however, must be done in the individual case. Age plays a less important part than the general condition.

Bundle Branch Block.—From 1942 to 1951, 100 cases of bundle branch block, in 61 men and 39 women, were diagnosed. Four forms were seen: typical branch block of the right and left sides, Wilson block, and left block of homophasic type. Ninety of the cases represented left bundle branch block. The average age of the patients at the time of diagnosis was 73.1 years; 40 patients were between 70 and 80. Forty-six deaths occurred during the first year after diagnosis. The diagnosis had been made at least five years previously for 15 of the 19 patients still living; one of the three who were still living 10 or more years after the diagnosis was made has been observed for 18½ years. The principal etiological factors are hypertension and coronary occlusion, with resulting enlargement of the heart and fibrosis. Lundh says that, since electrocardiographic examinations are not a routine procedure, many cases of bundle branch block are not discovered. The prognosis follows that of the basic disease. Bundle branch block is not incompatible with long life and some physical activity, but such cases are rare.

Ectopic Stenosis of the Aorta.—Only 21 cases of subisthmic, ectopic stenoses of the aorta, either thoracic or abdominal, have hitherto been reported. Many of the earlier cases were diagnosed only at autopsy, but the anomaly can now be demonstrated by angiocardiography. Surgical correction has been attempted in six cases. In five cases the stenosis was in the lower thoracic aorta but above the diaphragm, while in the sixth case it involved the lower end of the abdominal aorta. Arterial grafts may be successfully used to replace the narrowed segment of the thoracic aorta, but the only method promising a cure in stenosis of the abdominal aorta is the creation of some kind of a shunt to carry the blood from the aorta past the stricture, thus counteracting hypertension. This method was used by the author in the first operation for ectopic aortic stenosis performed in Europe; the splenic artery was successfully anastomosed to the aorta and the postoperative course during the first three days was good. Then, however, the patient's general condition, which was complicated by heart failure and renal impairment, deteriorated, and on the fifth postoperative day she died. Early intervention, before cardiac disturbances associated with increasing hypertension or nephritis have had time to appear, is apparently essential; the procedure, which is at best an artifice, cannot be expected to succeed under any but favorable conditions.

Thromboembolic Disease in Patients with Mitral Involvement.—An impaired mitral valve is not only indicative of rheumatic fever, which may become active again at any time, and a site of predilection for secondary infection but is also an essential factor in the development of thromboembolic disease characterized by fever, repeated emboli, and symptoms of venous thrombosis. The fever is usually constant but moderate, with occasional peaks coinciding with embolic attacks, which may be either pulmonary or arterial. The classical picture of infarct presented in acute episodes of pulmonary embolism is unmistakable; at times, however, the condition may be clinically silent, or the symptoms may be limited to the recurrence of dyspnea, the abrupt appearance of right ventricular failure, or a hemorrhagic, inflammatory pleural effusion. Arterial embolism appears especially at the aortic bifurcation or in the lower limbs; less frequent than pulmonary embolism, it is usually a late manifestation and consequently carries a poor prognosis. Patients with mitral disease should be given routine examinations of the veins of the leg, especially those in the calf, where the earliest signs of thrombosis are found. The symptoms constituting this syndrome are due partly to the hemodynamic disturbances resulting from the valvular defect and partly to the hypercoagulant effect of the drugs used in treating the heart condition (digitalis and mercurial diuretics and even cortisone and corticotropin). The hypercoagulability of the blood may be seen on comparison of the prothrombin rate with the results of in vitro heparin tolerance tests. Transient increases in the alpha and gamma globulin fractions apparently coincide with periods of hepatic congestion and renewed activity of the thrombosing process respectively. Thromboembolic disease usually progresses by repeated embolic attacks, although it may be either acute or chronic. Anticoagulants should be given routinely to all patients in whom mitral affections are complicated by thromboembolic disease; discovery of hypercoagulability in itself constitutes an indication for their use. Patients with cardiac arrhythmias, especially those presenting the syndrome of enlarged left atrium, complete arrhythmia, and fever, should also be given antifibrillant medications such as dihydroquinidine. Excellent results have been obtained in patients treated by this method; embolic attacks ceased and the temperature was immediately reduced when sinus rhythm was restored.

*Bufo-Reaction with Blood and Urine for Biological Diagnosis of Pregnancy. A. De Marchi and G. Carrain.—p. 125.

Bufo Vulgaris Test for Diagnosis of Pregnancy.—At the obstetric and gynecological clinic of the University of Padua the biological test for pregnancy is made on the Bufo vulgaris toad. This toad reacts well to gonadotropins, is less expensive than the animals that are usually used for this purpose, and can be utilized again four to five days after the test. Another feature of this test is that blood serum rather than urine is utilized. The authors made a comparative study of the results with urine and with blood serum. More accurate, quicker, and more intense results were obtained with the blood serum, probably because of a constant and greater concentration of chorionic gonadotropic hormones in the serum. There were five falsely negative reactions when 2 cc. of the urine from 281 pregnant women were injected into the toads, whereas the reactions were always positive when 2 cc. of the blood serum from 508 pregnant women were injected. There was one falsely positive reaction when 2 cc. of the urine from 10 men were injected into the animals. The response was always negative when either blood serum or urine of nonpregnant women was injected. Thus, the results were accurate in 100% of the cases in which blood serum was used but in only 99.43% of the cases in which urine was used. Acidosis developed frequently after the injection of urine, and the animals died during the experiments. The blood serum, however, proved completely atoxic for the animals.

*Iodine Prophylaxis and Iodine Deficiency Concept: Study of Thyroid Conditions in Children of School Age in Several Swiss Villages. H. J. Wespi.—p. 452.

Iodine Prophylaxis and Iodine Deficiency.—In Wespi's experience, a reduced incidence of goiter is noted earlier in children than in adults. He studied the thyroid of school children in several villages of the Swiss cantons of Zurich and Aargau where examinations carried out in 1912 had shown the incidence of goiter was 55% in the Aargau villages and 47% in the Zurich villages. In 1952 the incidence of goiter had been decreased to 17% in the Aargau villages and to 1% in the Zurich villages. The decrease in the incidence of goiter in the Zurich canton is considered proof of the prophylactic effect of iodized salt, since considerably more iodized salt had been used for seasoning and cooking purposes in the canton of Zurich during the last 20 years than in the canton of Aargau. The reduced incidence of goiter was manifested not only by the disappearance of external evidence of an enlarged thyroid but also by decrease in the number of thyroids that could be palpated. The author agrees with Curtis and Fertman that the human optimal iodine requirement ranges between 100 and 200 mcg. The amount of iodine in the iodized salt used for seasoning and cooking purposes remains within the range of this "biological" dose. The fact that the goiter-preventing effect of the iodized salt is initiated with the biological dose and not only after administration of larger doses clearly demonstrates that the iodine prophylaxis results from prevention of iodine deficiency rather than from a pharmacological effect similar to that of quinine in malaria. Iodine deficiency may result from several causes in man. Primary deficiencies may be due to exogenous factors such as lack of iodine in soil, water, air, and food in regions endemic for goiter. Endogenous factors may be increased requirements in pregnancy and during growth, and climatic, hygienic, and nutritional influences. Secondary deficiencies or disturbances of utilization may be due to disturbances of thyroid hormone synthesis or substances such as fluorine and bromide and of thyroxin-like substances. Heredity may also play a part.

BOOK REVIEWS

1953 Medical Progress: A Review of Medical Advances during 1952. Morris Fishbein, M.D., editor. Cloth. $5. Pp. 301. Blakiston Company (division of Doubleday & Company, Inc.) 575 Madison Ave., New York 22, 1953.

This new publication is a yearbook reviewing recent progress in various branches of medicine and surgery. There are 16 chapters by 24 contributors dealing with special fields and a final chapter in which the editor evaluates important advances. Some chapters begin with a historical account of previous developments to aid the interpretation of current changes; others have only occasional reference to past achievements. Thus the book includes more than a review of the preceding year. There is some overlapping, particularly with regard to drugs, which are mentioned in the chapters dealing with the diseases in which they are employed as well as in a chapter devoted entirely to new and important drugs. All except this chapter and the first and last are followed by a bibliography. The general index could be improved by cross references to synonyms. From chapter to chapter there is no uniformity in drug terminology, which may be confusing to readers not thoroughly familiar with it. Thus hydralazine hydrochloride appears only under the chemical name 1-hydrazinophthalazine and the brand name Apresoline, for the base, in the chapter on arterial hypertension. The format and binding of this book are pleasing, and it should be helpful to practicing physicians for reviewing background and current progress in most of the branches of medicine and surgery.

Hoppe-Seyler Handbuch der physiologisch- und pathologisch-chemischen Analyse für Ärzte, Biologen und Chemiker. Herausgegeben von Konrad Lang und Emil Lehnartz, unter Mitarbeit von Günther Siebert. Band V: Unterschung der Organe Körperflüssigkeiten und Ausscheidungen. Bearbeitet von F. Bruns, et al. Tenth edition. Cloth. 168 marks; subscription price, 134.40 marks. Pp. 938, with 44 illustrations, Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

The fifth volume (which has preceded the others) of the 10th edition of this standard work deals with the analysis of normal and pathological body fluids, organs, and secretions. It should be welcomed, because the ninth edition is out of print as well as out-of-date, and the corresponding work in English (Peters and Van Slyke, "Quantitative Clinical Chemistry," Vol. 2, Methods) was published in 1932. In typical "Handbuch" fashion, the work is a collection of monographs by experts. Body fluids are covered by K. Hinsberg and his associates, organs by Cremer and Führ, milk by W. Diemair, tumors by C. Dittmar, and drugs and poisons by K. Gemeinhardt. Topics are treated briefly, and the reader is referred to the original literature. The articles cited are in a variety of journals published throughout the world. They date through 1952, although most articles appeared from 1930 to 1950. The material is organized logically. Directions for the assays are short but complete, and the German is simple. There are exhaustive author and subject indexes. Printing, paper and binding are of excellent quality. Clinical chemists, pathologists, and biochemists will find this work worth while.

Functional and Surgical Anatomy of the Hand. By Emanuel B. Kaplan, M.D., F.A.C.S., Assistant Professor of Anatomy, College of Physicians and Surgeons. Columbia University, New York City. Cloth. $10. Pp. 288, with 132 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

It is proper that the hand be considered as an organ, and with this thought in mind the author presents its functional and surgical anatomy. The importance of the hand as a medium through which we are in contact with the surrounding world is stressed. Function is studied along the lines of comparative anatomy, particularly with that of the hands of anthropoid apes. Direct observations revealed that the differences are usually small and at times indistinguishable.

The comparative length of the thumb and the almost constant presence of the flexor pollicis longus is the most characteristic feature of the human hand. This combination permits better opposition and greater stability. The thenar eminence of the gorilla and chimpanzee are almost identical with that of the human hand. For the sake of study, the author has divided the hand artificially into three functional units: the thumb, the index and middle fingers, and the ring and fifth fingers. This is a rather novel and helpful approach. In depicting the thumb as an independent unit, he has incorporated the two phalanges, the first metacarpal, and the greater multangular and navicular bones.

A few minor faults do not seriously detract from this work. There is a lack of illustrations from living material, for example, Dupuytren's contracture shown in figure 120 is that of a shrunken hand of a cadaver. An attempt to make legends clear has resulted in use of too large a size of type. Imbalance between letter size and specimen is seen in figure 61, in which the specimen has been reduced to such a degree that the structures are difficult to identify. The use of color illustrations would have enhanced this text. The book can be recommended to anyone interested in anatomy, function, and surgery of the hand.

The Surgery of Pancreatic Neoplasms. By Rodney Smith, M.S., F.R.C.S., Surgeon, St. George's Hospital, London. Awarded by Council of Royal College of Surgeons the Jacksonian prize for 1951. Cloth. $7. Pp. 157, with 111 illustrations [Williams & Wilkins Company, Mount Royal and Guilford Ave., Baltimore 2]; E. & S. Livingstone, 16 and 17 Teviot Place, Edinburgh 1, 1953.

This concise and well-illustrated book covers most aspects of surgery for tumors of the pancreas. The first section deals with anatomy, physiology, history of pancreatic surgery, and classification of pancreatic neoplasms. The second section thoroughly develops the clinical and surgical aspects of carcinomas of the ampulla of Vater and of the head of the pancreas. The third section deals with less common but interesting and important neoplasms. The author has carefully evaluated the problems connected with diagnosis and surgical treatment. This book will prove valuable reading for surgeons.

Progress in Clinical Medicine. By various authors. Edited by Raymond Daley, M.A., M.D., M.R.C.P., and Henry Miller, M.D., M.R.C.P., D.P.M. Second edition. Cloth. $6.50. Pp. 426, with 43 illustrations. J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London W.1; [John de Graff, Inc., 64 W. 23rd St., New York 10], 1952.

In the second edition of this book the editors have omitted many of the previous subjects, which were particularly of military interest, and have added sections on cerebral angiography, electrolyte and water balance, cortisone and corticotropin, hypersplenism, toxoplasmosis, electrocardiography, parkinsonism, and the newer antibiotics. In discussing the many aspects and problems of internal medicine no attempt is made to cover complete systems. The material covered should be of general interest to the specialist in internal medicine as well as to the general practitioner or medical student who is at the intern or residency level. The subjects are as well covered as can be expected in a book of this size. There are 43 good illustrations. The style of writing is generally good, and the simplicity of most of the articles makes the volume extremely readable. On the whole, the book can be recommended.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

QUERIES AND MINOR NOTES

ODOR OF SWIMMING POOL WATER

To the Editor:—*The source of our swimming pool water is a natural hot water well, which provides water of about 87 F with a definite odor of hydrogen sulfide. A chemical analysis of this water revealed manganese, 0, sulfides, 0.1 ppm, nitrate, 0, phosphate as PO_4, 0.14 ppm, silica, 28 ppm, and ammonia as N, 1.0 ppm. It has been discovered that the chlorine demand of this water is 2.2 ppm, but 16 ppm is required to produce a free chlorine residual without chloramine. It is the opinion of a medical committee that this water may contain chemicals that are injurious to the mucous membranes of the nose, throat, and eyes. Inasmuch as we have considerable difficulty with rhinopharyngitis and conjunctivitis in our swimmers, we would like your opinion on the chemical content of the water.*

Warren B. Ross, M.D., Nampa, Idaho

Answer.—The key to this difficulty may reside in the hydrogen sulfide content of the water, which possibly may be appreciably higher than the value reported. This gas potentially is an eye irritant even in trace concentrations. Hydrogen sulfide combines with the added chlorine and thus in part accounts for the high chlorine requirements. This reaction eventuates in a lowered pH, and this acidity may contribute to the eye irritation. The condition might be improved by extensive aeration of the water prior to introduction into the pool. This step will contribute both to removal of the hydrogen sulfide and to acid reduction. From any swimming pool and particularly under circumstances of low temperature, conjunctivitis and nasopharyngitis can arise and not always from either bacterial or chemical contamination. In part this may be related to excessive heat losses from the body. Chiefly this situation is one for the appraisal of the skilled sanitary engineer.

TREATMENT FOR CORAL SNAKE BITE

To the Editor:—*Please outline treatment for the bite of the coral snake (Micrurus).*

Jack Mickley, M.D., Hollywood, Fla.

Answer.—In considering treatment for bites of the coral snake, it must be borne in mind that this reptile is the only representative in America of the family of snakes known as Micruridae, in contrast to the large number in this country that belong to the family Viperidae, which includes rattlesnakes, copperheads, and moccasins. The principal constituent of the venom of Micruridae is a neurotoxin that kills primarily through paralysis of the respiratory center in the medulla. The best known of these venoms is cobra venom, which is now employed therapeutically to some extent. Vipers, on the other hand, produce a venom that is rich in hemotoxins or blood poisons, of which some are hemorrhagins, others are thrombins, which promote blood clotting, and still others are cytotoxic in character. The rational treatment for coral snake bite would of course be the administration of a suitable antivenin, but this consultant is not certain whether such an antivenin is available. If not, the following procedure should be followed: A tourniquet is applied locally to impede further absorption of the venom through the veins and lymphatic vessels. At the same time, with local procaine anesthesia, multiple incisions are made with a razor blade, as much poison as possible is removed by suction, and the wound is irrigated with sodium chloride or potassium permanganate solution. Under no circumstances should permanganate be injected. The tourniquet should be released every 30 minutes to prevent development of gangrene. Mild sedatives, such as phenobarbital or small doses of alcohol, may be administered to relieve pain, and psychotherapy is useful to prevent the patient's becoming panicky. It is not wise to employ morphine or other powerful narcotics, because they depress the respiratory center, which is the most vulnerable organ in coral snake venom poisoning. On the contrary, respiratory stimulants, such as hot coffee or tea, caffeine and sodium benzoate, or pentylenetetrazol (Metrazol), may be administered in severe cases. Artificial respiration may be indicated until the venom is at least partially destroyed in the body. Heart stimulants and other analeptics are administered as necessary. If the occurrence of systemic infection from the bite is possible, cautious use of sulfonamide or antibiotics must be considered. Recent reports of the possible usefulness of antihistaminics and cortisone or corticotropin (ACTH) are not yet convincing but should be borne in mind.

LARVA IN INTESTINAL TRACT

To the Editor:—*For some time, a patient has been passing fly-like organisms resembling the drone bee with a long tail. The organism has been described by a pathologist and an entomologist as Tubifera tenax. The condition is apparently rare. If you have any information relative to treatment, we would be pleased to receive it.*

H. F. Hooker, M.D., Danville, Ill.

Answer.—Tubifera tenax is probably the preferred name for a fly of the "rat-tailed larva" group that has been often referred to as Eristalis tenax and occasionally as Eristalomyia tenax. The larva of this fly is not an obligate parasite. It is usually found in water contaminated by sewage and other foul organic matter. The larva, which is extremely resistant to adverse conditions, is apparently able to develop in, and traverse, the gastrointestinal tract. There are on record probably more than 30 cases of human myiasis caused by the larvae of this fly or by the larvae of related species. There are also a number of cases reported in domestic animals.

Treatment for the removal of these larvae has been varied. Among the treatments recorded are jalap, aloe, mild mercurous chloride (calomel), rhubarb, Creolin (a mixture of coal tar phenols and oils) and hot water, santonin, mercury, intestinal antiseptics, and hexylresorcinol. Swartzwelder and Cali (*Am. J. Trop. Med.* **22:**159-163, 1942) mentioned the last-named drug as being given to a child 6 years old, after she had coughed up an insect larva and had passed a small worm after an enema. The dose for the child was three Caprokol (hexylresorcinol) tablets of 0.2 gm. each. It was stated that within a few hours after treatment seven rat-tailed maggots were passed and that some of the larvae were visibly affected by the treatment.

NASAL MEDICATION IN CORONARY PATIENTS

To the Editor:—*Most of the antibiotics for local nasal use embody a vasoconstrictor. Which one is the least harmful medication in cases of coronary sclerosis?*

Max J. Schroeder, M.D., New York.

Answer.—The local use of antibiotics for the control of rhinitis, in the presence of coronary sclerosis, is rarely contraindicated. Even the solutions containing vasoconstrictors in the dilution ordinarily encountered are harmless. Only in extreme instances of coexisting coronary sclerosis and severe hypertension are vasoconstrictors to be used with caution. Even then it is questionable whether such medication elevates blood pressure appreciably or has any adverse influence on the coronary vessels.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

MEDICOLEGAL EXPERIENCES UNDER THE OHIO CORONER'S SYSTEM

Kurt E. Landé, M.D.
and
Garrett Boone, M.D., Hamilton, Ohio

On Oct. 12, 1945, recodification of the laws concerning the duties of the county coroner in Ohio was made effective. This final step in a long-drawn-out legislative process aimed at modernization did away with many antiquated and outdated laws and replaced them with rules reflecting more advanced concepts of investigation of the cause of death under doubtful circumstances. While still retaining the traditional office and name of coroner, the revised Ohio code allows the development of a coroner's system that resembles the medical examiner's system enacted in the last few years in Maryland, Virginia, and Georgia. These were modeled after the medical examiner's offices that have functioned successfully in Massachusetts, New York City, and Essex County, N. J., for a long time.

In Ohio, the coroner must be a physician. He receives an annual salary based on the population figure of the county in which he serves, and he is elected to office either as a true party candidate or as an unopposed, nonpolitical candidate. Each county coroner acts independently since there is no central agency, as in Baltimore, that coordinates and scrutinizes reports and that supervises the county medical examiners.[1]

Under sections 28855-5 and 28855-6 of the Ohio code, the duties of the coroner have been expanded and strengthened by the provision that "when a person shall die as a result of criminal or other violent means, or by casualty or by suicide, or suddenly when in apparent good health, or in any suspicious or unusual manner, the physician called in attendance or any other person finding the body or acquiring first knowledge of such death, shall immediately notify the office of the coroner and submit any information in his possession which may be requested by the coroner. . . . In such cases, if a request for cremation is made, the funeral director called in attendance, shall notify the coroner immediately. The coroner or his deputy, if he deems it necessary, shall take care of the body and may authorize an autopsy. The coroner may conduct an inquiry, subpoena witnesses etc. and shall make a report to the county prosecutor. The coroner or the county prosecutor may order a body disinterred for exhumation." The law permits the establishment of suitable offices, laboratories, and equipment in the county for the use of the coroner, and it allows the coroner to appoint and to fix the salaries of assistant coroners, one to be designated chief deputy coroner, and pathologists and other personnel to assist him in his work. It allows coroner's laboratories to perform examinations for coroners in counties that do not have laboratory facilities.

COUNTY SURVEYED

The survey of the practical working of the new coroner's laws was undertaken in an Ohio county with a population of 147,203 according to the 1950 census. Two industrial cities, Hamilton and Middletown, contribute 60,000 and 35,000 members of the population respectively. Rich farmland, a number of smaller communities, and one college town, Oxford, determine the semirural character of the county. About 3.5% of the population are Negroes who live in the two cities and in the college town. The turnover of population is considerable, because of constant interchange of the common labor force between southern Ohio and the hills of Kentucky and because of the usual transfer of personnel in industry.

The new coroner replaced an elderly physician who had been in office, under the old, antiquated system, for about 20 years. After the new coroner had been in office for some time, the effect of the new code could be evaluated, and it was only after his election that sufficient records were available to permit valid conclusions on the extent of work accomplished.

RESULTS OF SURVEY

Since the center of the county's population is in and around Hamilton, the greater number of postmortem examinations were handled in that city. The two Hamilton hospitals have a combined bed capacity of 415 as compared with a capacity of 148 in the Middletown hospital; therefore, proportionally greater numbers of patients who became coroner's cases were treated in Hamilton than in the neighboring city (table 1). The total number of deaths in the county amounted to 1,405 in 1951 and 1,440 in 1952. The total number of cases investigated by the coroner, 305 in 1951 and 334 in 1952, are about 21 to 22% of all the deaths in the county; this is a desirable optimum of investigatory activity. About every fifth death was reported to the coroner and investigated. In the majority of instances, a telephone call to the attending physician or to the hospital authority in whose institution the patient died, either from accident or shortly after admission, was sufficient to preclude any further steps on the coroner's part. Nevertheless, the number of cases, not quite one per day, shows that, in a county of about 150,000 inhabitants, the coroner's office has ceased being a sinecure; even if a case is closed after only cursory investigation, a complete record must be made and kept on file.

TABLE 1.—*Coroner's Cases in Butler County, Ohio, from 1948 to 1952*

Year	Fatal Car and Railroad Accidents	Other Fatal Accidents	Suicides	Homicides	Death from Natural Causes	Rape and Abortion	Poison	Cases Investigated	Autopsies: Hamilton	Autopsies: Middletown	Autopsies: Total
1948	37	23	6	3	140	..	1	210	18	..	18
1949	40	25	12	5	184	..	..	266	24	5	29
1950	60	41	6	3	218	..	3	331	25	17	42
1951	49	34	16	2	203	..	1	305	39	12	51
1952	49	50	17	3	215	..	..	334	34	16	50
Total	235	173	57	16	960	..	5	1,446	140	50	190

The five year total of 190 autopsies amounts to 13.1% of the coroner's cases. In 1951 and 1952 alone, the percentage was 15.7. Several factors have influenced the gradual increase of postmortem examinations. First, only since 1949 has a part-time pathologist been available at the Middletown hospital, and only since early 1950 has a full-time pathologist been available. Secondly, Mercy Hospital in Hamilton has been approved by the American Medical Association for intern and resident training and has, therefore, been more interested in raising its autopsy rate. For that reason, more coroner's cases have been autopsied at that hospital than the one in Middletown that does not employ medical house officers (table 2). In Hamilton, physicians have asked for and the coroner has consented to authorizations for autopsy in cases of traffic accidents, sudden death from natural causes, and other pertinent causes that perhaps would not have been subjected to examination if the hospital and house staff had not been interested. Furthermore, starting on Jan. 1, 1950, the coroner's pathologists in Middletown and Hamilton have been retained on a salary. This gives the coroner freedom to order autopsies whenever he considers them necessary, whereas formerly it was difficult to elicit payment from county authorities for the autopsies, even at the very low statutory Ohio rate of $20 per case (including written report and microscopic examination). Formerly the majority of coroner's autopsies requested for patients dying in one of the hospitals were not charged for in order to avoid any potential argument on the part of the county commissioners as to the need for such postmortem examination. It was felt by both the coroner and the pathologist that the development of an efficient coroner's service is a long-range program and that only gradual education of the public and its political representatives would and could lead to steady improvement.

TABLE 2.—*Coroner's Autopsies in Butler County, Ohio, from 1948 to 1952*

* Hamilton.
† Middletown.

From this point of view, the annual salary of $500 for the Middletown and $700 for the Hamilton pathologist was a step in the desired direction. Even so, one cannot claim that the money spent by the county for coroner's autopsies, listed in the county budget under the heading county morgue, represents a fair compensation for time and work involved in more than 30 autopsies per year performed by the Hamilton pathologist and about 15 by the Middletown pathologist. In 1952, the coroner received $2,233.05 for his own services and $1,466.08 for clerical and other expenses. Since the coroner's tasks often necessitate prolonged absence from his medical practice, it is not surprising that smaller counties in Ohio have had difficulty finding a physician willing to assume the duties of the coroner's office. It is not only the low pay offered that makes a physician think twice before he puts public interest before his own personal advantage but also the knowledge that for less vital but politically more important county offices rather lavish sums are available. This is especially true when one learns that in 1952, an election year, the county budget allowed only a total of $4,882.41, including the pathologists' salaries, to the coroner's office but $14,571.91 to the county dog catcher. If, under the present set-up, public-minded physicians take on the coroner's duties in the smaller counties, it is mainly with the realization that the slow process of educating the public to the practical importance of a well-functioning, up-to-date coroner's office has to be undertaken by some member of the medical profession. For years to come, those engaged in coroner's work will perform their task spurred more by their genuine interest in this fascinating field than by the opportunity to increase their personal income easily and conveniently.

CAUSES OF DEATH INVESTIGATED

The preponderance of coroner's cases were sudden deaths from natural causes. This is also the group in which the largest number of autopsies were performed; this incidence is similar to that of the whole country. Heart disease, mainly the direct or indirect sequelae of coronary arteriosclerosis, is by the far the leading cause of sudden, unexpected death. Degenerative diseases of the vascular system run a close second, with cerebral hemorrhages and ruptured congenital, cerebral, or arteriosclerotic aortic aneurysms frequently represented. Vascular accidents are so often brought to the coroner's attention because of their involvement in traumatic events at home, at work, or on the street. If an elderly person falls and contracts a fracture, quite often questions are raised concerning insurance, compensation, eventual liability of a third party, or justified or unjustified accusations of wilful or unintended neglect. Problems of this kind make an autopsy desirable, even if death occurs many months after the real or supposed accident took place.

Fatal hemorrhages of clinically unknown origin are another category encountered quite often; rupture of esophageal varices, hemorrhages from silent peptic or duodenal ulcers, and hemoptysis from unrecognized or neglected tuberculous cavities have been found. Sudden death from tuberculosis of any kind is not the only indication of the epidemiological importance of coroner's autopsies. Autopsies of children who died unexpectedly after attending a social function revealed pathological changes typical of Waterhouse-Friderichsen syndrome (fulminating meningococcic meningitis). Prompt prevention of its spread among contacts was initiated on the basis of the autopsy findings. The question of rabies came up twice, but the clinical suspicion was not confirmed anatomically. An upper respiratory infection that caused the death of two young brothers and clinically resembled malignant diphtheria but that was proved bacteriologically to have been caused by highly virulent hemolytic staphylococci prompted an extensive investigation by the county health authorities.

The new code fortunately provides that the coroner may proceed with postmortem examination in the instance of sudden death from suspected communicable or infectious diseases even if the family of the victim denies permission. Occasionally, the reluctance of the family to concede the value of an autopsy changes when the sudden death of one of its members is explained to eliminate any guilt feelings. This was dramatically demonstrated when it was proved that a 5-year-old boy, who died shortly after his father had given him a mild spanking, had suffocated from a malignant thymoma filling the whole mediastinum and compressing the trachea and esophagus almost completely.

Deaths caused by anesthesia are very tragic particularly when they occur in cases of elective or minor surgery. The coroner orders autopsies in most of these instances in order to rule out any other cause of sudden death and to establish anatomic facts in case of later unfounded accusations. In the case of a young woman who died before a thyroidectomy was begun, autopsy revealed unsuspected bilateral, huge adrenal cortical carcinomas. It is in cases of this kind that the Ohio code is unique in granting the coroner the undisputed right to have an autopsy performed.

Accidents are the next most important group of coroner's cases, with automobile accidents the commonest. Railroad accidents, however, are, in this county, far from rare and are frequently the result of unprotected railroad crossings at which drivers or pedestrians either half-asleep and/or intoxicated are caught by a train. Industrial accidents are encountered in the usual frequency, in spite of existing safety programs in the steel and paper mills, machine tool factories, and foundries. In the accident group, farm accidents, caused by machinery, livestock, or a combination of both, comprise a significant number. Among the industrial accidents, a few cases of poisoning have occurred; persons overcome by poisonous fumes while cleaning boilers have fallen into vats filled with concentrated acids or alkali solutions. In one case, an alcoholic derelict was exposed, while in temporary jail custody, to great quantities of delousing fluid. The police did not realize that it was dangerous for this man, who happened to suffer from a chronic, weeping generalized eczema, to absorb the fluid. Death resulting from accidental ingestion of carbon tetrachloride mistaken by a woman for a headache medicament while she was mildly intoxicated was misinterpreted clinically as happens so often when alcoholism is the well-known and obviously leading symptom. Two excellent discussions of accidental poisoning have been published recently.[2]

Although true homicides have been infrequent, suicides are fairly common; among them have been several homicide-suicide situations. Too many sleeping pills, gunshot wounds, and carbon monoxide are employed more often than hanging. Rape and abortion cases with fatal outcome have not numbered in the coroner's material since 1948. One case of death caused by septic abortion came to autopsy in 1945 and one in 1947. This infrequency does not mean that the county does not have its full quota of spontaneous and criminally induced abortions, but that those who start or perform them are apparently familiar with a certain degree of aseptic technique or have been lucky so far.

THOSE INTERESTED IN AUTOPSY RESULTS

The postmortem examination of many of the coroner's cases is very often of considerable interest to insurance carriers. For instance, a death originally reported to the coroner as accidental was conclusively proved to have been suicidal through the coroner's persistent investigative efforts. In spite of the obvious advantages to insurance carriers from an ever-expanding autopsy program, encouragement from that group has been singularly lacking. One often has the feeling that much future grief and litigation could be averted if the respective insurance carriers would show as much interest in having autopsies performed routinely as they demonstrate when they find it particularly advantageous to utilize the coroner's findings. One sometimes wonders whether there could not be devised a procedure in which, in cases involving considerable amounts of money, those obviously profiting by the coroner's efforts could be made to share the expenses with the county for the coroner's work. Even without this financial consideration, one of the educational goals for which the coroner and his associates are striving is to change the passive attitude of these insurance companies to a more active, cooperative interest.

Without the close cooperation of the city police department, the sheriff's office, and the prosecuting attorney and his staff, no coroner could ever hope to perform useful work. They are by the same token the very groups who are cognizant of the help they receive from the coroner. In Butler County, as almost everywhere, these agencies and their representatives cooperate closely and to full mutual satisfaction with the coroner and his associates. A good deal of tact and diplomacy is needed, however, to prevent the coroner's being prevailed on and becoming the honorary but nevertheless very busy police and fire department attendant to patients who are alive and who have only a long-range relationship to the function of the coroner's office as outlined by law.

An alert physician serving as coroner and a pathologist serving under him, both of whom are well versed in forensic procedures, are indispensable in modern crime detection. Even in Butler County, enough cases occur in which only a thorough autopsy provides the basis for the further work of the police force that culminates in apprehension of a suspect and a later court trial. Or, in reverse, a postmortem examination may disclose, as in one Butler County case not long ago, that a woman beaten by her common-law husband did not die from the blows that were relatively minor in force but from a preexisting, extensive brain tumor. This finding closed the case as far as the law enforcement agencies were concerned and saved the county much unnecessary expense. Similarly in noncriminal cases only thorough and expert investigation can allow the decision of whether a man who, as a house painter, fell from a high scaffolding was the victim of a coronary thrombosis or whether a foundry worker who died at work suffered from an organic disease caused or aggravated by his occupation. Cases like these, which could be multiplied by numerous other random examples, belong in the coroner's field as much as do acts of pure violence, the investigation of which was the original basis for the task delegated to the coroner.

SUMMARY AND CONCLUSIONS

At present, as our five year survey shows, the coroner's office has the inherent opportunity for steady growth and organic expansion. For unusual circumstances like the eventual need for toxicological examination, laboratories such as those of the Kettering Institute in Cincinnati are available for Butler and other neighboring counties. Establishment of a centralized coroner's or medical examiner's system, similar to that of Maryland or Virginia, would appear justified and necessary only for those counties in which the service of a coroner's pathologist are not available. Since one of the main goals, in addition to steady and expanding routine work, is education of the general public on the local and county level as to the important role a well-functioning coroner's office plays in their welfare, it seems that for now the present Ohio system fulfills the existing needs and serves its purposes well.

DIAGNOSTIC SIGNIFICANCE OF BLOOD SUGAR FINDINGS

Christopher J. McLoughlin, M.D., Lester M. Petrie, M.D.
and
Thomas E. Hodgins, M.D., Atlanta, Ga.

During the past few years the American Diabetes Association has sponsored a Diabetes Detection Week throughout the entire country. Many screening tests have been devised for finding the unknown diabetic, and a tremendous amount of work has been done on diabetes detection. The late Dr. James Edgar Paullin, in 1949, challenged the Georgia Department of Public Health to incorporate a test for abnormal carbohydrate metabolism in their Voluntary Multiphasic Health Test program, which included a chest roentgenogram, a test for anemia, and a serologic test for syphilis. The Anthrone method of blood sugar analysis was developed,[1] and, in 1950, the rapid screening of large numbers of patients was begun.[2]

Since April, 1950, about 600,000 persons in the state of Georgia have voluntarily submitted to this screening procedure for abnormal carbohydrate metabolism. A report on almost 250,000 of those screened during the past 18 months was made at a recent meeting.[3] Each person tested was classified as having an abnormal (over 160 mg. per 100 cc. in two hours or over 160 mg. per 100 cc. at 45 minutes, but below 160 at two hours) or a normal (below 160 mg. per 100 cc. both at 45 minutes and at two hours) blood sugar metabolism on the basis of an initial screening test and a modified glucose tolerance test. In the last group reported, 4,524, or 1.87%, were referred to their private physicians as cases of abnormal carbohydrate metabolism. To obtain a clinical follow-up on all referred persons, a mimeographed sheet (reproduced below) containing a check list of known causes of

hyperglycemia was forwarded, with results of the screening tests, to the person's private physician. He was requested to mail the sheet back to the health department after making his diagnosis as to the probable cause of the abnormal carbohydrate metabolism.

Analysis of our reports (see figure) of these persons with abnormal carbohydrate metabolism as to age, sex, and race shows that prevalence of abnormal sugar metabolism increases markedly with the advance in age, with the highest incidence of 8.98% in the group of Negro women in the seventh decade. Note that there is a definitely higher percentage of abnormal carbohydrate metabolism in the Negro females and a lower prevalence in the Negro males. Over 70 years of age the incidence in Negroes decreases slightly, but in the white population there is a very definite increase.

Address......................................

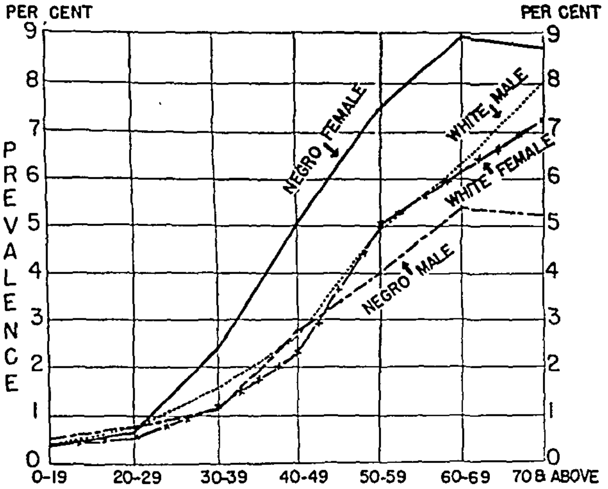
Revised Sept. 1951

Ga. Dept. of Public Health in cooperation with U.S.P.H.S.

There were 241,451 persons examined of whom 4,524, or 1.87%, showed some abnormality of carbohydrate metabolism and were referred to the physicians of their choice. In this group, 415, or 9%, gave a history of having known of a diabetic condition prior to taking the tests. This left 4,109 patients referred to physicians for further diagnosis. Of these, follow-up reports were submitted for 1,981, or 48.2%. We were interested in discovering what percentage of these patients referred would be diagnosed as having true cases of diabetes. Secondarily, we were interested in the various methods used by practicing physicians to determine the presence of diabetes. As we will show, a great deal of missionary work is yet to be done in training the average physician to make a diagnosis of diabetes mellitus.

Of the 913 patients classified by us as having borderline cases, 186, or 20.4%, were diagnosed by their physicians are being "new" diabetics. We classified 1,068 as having definitely abnormal tolerance curves by our screening tests, and 629, or 59%, were diagnosed as "new" diabetics. This gives a total of 815 new diabetics among the 1,981 reported. As will be demonstrated, however, there are, in our opinion, many cases of diabetes among the remaining 1,166 so-called "nondiabetics."

Among the laboratory procedures employed by physicians to substantiate or deny the presence of diabetes were (table 1) urinalyses, fasting blood sugar tests, postprandial blood sugar tests, glucose tolerance tests, including Exton-Rose tests, and other tests such as that for basal metabolism. The Folin-Wu method was used almost universally for blood sugar determination. No intravenous glucose tolerance tests or insulin tolerance tests were reported. Here, particularly, we would like to call attention to the fact that simple urinalysis or a fasting blood sugar test was used to substantiate or deny the presence of diabetes in more than 76% of all cases. In fact, more than 82% of the referred persons classified as nondiabetic by physicians were assured of the absence of this disease on the basis of no laboratory work at all, or nothing more reliable than a urinalysis or a fasting blood sugar test. It should be remembered that some of these referred patients had more than 400 mg. of blood sugar per 100 cc. on our screening or glucose tolerance tests.



Prevalence of abnormal sugar metabolism in 10 year age groups.

TABLE 1.—*Laboratory Procedures Reported by Physicians*

Total 1,981	"New" Diabetic 815 (41.2%)	"Nondiabetic" 1,166 (58.8%)
Physician's Primary Laboratory Procedure:	No. of Patients "New" Diabetic	No. of Patients "Nondiabetic"
Urinalysis	419 (51.5%)	698 (60.0%)
Fasting blood sugar...............	210 (25.8%)	182 (15.6%)
Postprandial blood sugar..........	19 (2.3%)	21 (1.8%)
Glucose tolerance	161 (19.8%)	191 (16.4%)
Other *	6 (0.7%)	74 (6.3%)

* Usually history and physical. Three patients had basal metabolism determinations.

According to the check lists submitted by physicians (table 2), among the 815 patients given diagnoses of diabetes, 178 were overweight, 104 had associated arteriosclerosis, and 75 were in the old age group (which coincides rather closely with the percentage of diabetics previously reported [3] in the older age groups). Among these 815 new diabetics, 274 had one or more diagnoses other than diabetes checked by their physicians.

Among the 1,166 persons classified by physicians as having a condition other than diabetes as a primary reason for the abnormal blood sugar metabolism, 296 were overweight, 184 had arteriosclerosis, 108 were in the older age group, and 115 had their abnormal survey test explained as being due to a low carbohydrate diet. In this nondiabetic group of 1,166 cases, 25% had three or more diagnoses; 72 patients were checked as having five or more concomitant diseases and 125 as having other diseases, such as hypothyroidism, nephritis, chronic constipation, and low renal threshold, or as having a condition due to ingestion of too many cola drinks or too many starches. Even digestive glycosuria was mentioned as a cause of an abnormal two hour blood sugar level. There were 443 diagnosed as having no disease, although only six glucose tolerance tests were run on this entire group; no other postprandial blood test was made; 162 fasting blood sugar determinations were made, and the remaining 275 had diabetes ruled out by means of urinalysis and so-called "clinical judgment." The diagnosis of no disease was made on the 162 tested with fasting blood sugars, despite the fact that in 42 cases the fasting blood sugar was over 170 mg. per 100 cc.

COMMENT

As a result of the screening tests for diabetes, only 41.2% of those referred to physicians as having an abnormal carbohydrate metabolism were diagnosed by their physicians as having true diabetes. The greater percentage of referred patients were considered nondiabetic by a series of tests, which, from every standpoint, were inadequate to rule out this condition. Therefore, in view of the apparent dependence of the practicing physician on thoroughly unreliable tests, we feel that further instructions in the proper method of diagnosis of diabetes mellitus should be included in any information sent to physicians when patients are referred. We must agree with McCombs and Finn [4] that the education of the physician is essential if we are to take advantage of the benefits of the case finding surveys. Even though only 815 of these patients were confirmed by their physicians' reports to us as being diabetic, we feel that these screening surveys are worth while. We believe that many of those diagnosed, or in our opinion misdiagnosed, as nondiabetic will in a year or so prove to be suffering from this disease.

SUMMARY AND CONCLUSIONS

We have demonstrated in Georgia an effective method for screening large cross sections of the population on a voluntary basis. It has been shown there is a definitely higher prevalence of abnormal carbohydrate metabolism in the Negro female and that in all older age groups the incidence appears to be much higher than previously anticipated. Too many physicians are still employing a fasting blood sugar test or urinalysis as a diagnostic procedure for diabetes. An educational program is being developed in Georgia to bring the physicians up-to-date on the diagnostic criteria of this disease.

Symptoms of Potassium Deficit.—Potassium is the chief cation of muscle cells and of most other cells, since it is present in the *intra*cellular fluid. Sodium, on the other hand, is the chief cation of *extra*cellular fluids of the body. Any considerable replacement of sodium by potassium in the extracellular fluids is accompanied by serious disturbances and may be fatal. No other cation can entirely replace potassium in the intracellular fluid without interfering to a definite extent with the functional activity of the cell. . . . Potassium concentration of normal serum is 16 to 22 mg. per 100 cc., averaging 19 mg. While there is little or no sodium in the erythrocytes, the average concentration of potassium in them is about 420 mg. per 100 cc.

Absorption of potassium, under normal conditions, occurs almost solely from the gastrointestinal tract, but less than 10 per cent of potassium elimination occurs via the intestinal tract. Large quantities of it are so eliminated, however, in patients having diarrhea, but this excess may be due, in large part, to failure of reabsorption of digestive fluids rather than entirely to failure of absorption of the ingested salts. About 90 per cent of excreted potassium is eliminated in the urine. . . . The usual symptoms are general weakness, lassitude, diffuse atonicity of the intestinal tract with ileus, and cardiac irregularities, and hypotension. The severity of the symptoms and signs of potassium deficit are related to the serum potassium level. Decreased serum potassium effects neuromuscular physiology, the cardiac muscle, and the smooth muscle of the gastrointestinal tract.

All stages of change, from mere weakness to complete paralysis of the muscles of the trunk and extremities, may occur in the individual when the serum potassium level falls below 8 to 10 mg. per 100 cc., or 2.05 to 2.56 mEq. per liter. Changes in conduction, irritability, and contractility of cardiac muscle occur when there are potassium levels under 10 to 12 mg. per 100 cc. (2.56 to 3.07 mEq. per liter). These changes are manifested by abnormalities in the electrocardiogram. Clinically, the doctor may note systolic murmurs, gallop rhythms, cardiac dilatation, and hypotension. When potassium deficits are severe, cardiac arrest and death may occur.—Gail Gar Lyai Li, M.D., Hypopotassemia, as Encountered on a Gynecology Service, *American Journal of Obstetrics and Gynecology*, June, 1953.

INFLUENCE OF PREGNANCY, LACTATION, GROWTH, AND AGING ON NUTRITIONAL PROCESSES

Tom D. Spies, M.D., Birmingham, Ala.

Disease is as old as living matter. From time eternal, man has sought means of easing his pain, relieving his disabilities, and discriminating between the foods that are good for him and those that are not. His progress has been made through a process of trial and error. It is the physician's duty to devise ways and means of aiding him. In this report I will discuss how the physician can best make use of his opportunity.

The cells of the human body, like all other living things, must adapt, grow, and reproduce. By the time one has become a mature adult, he has had perhaps thousands of illnesses, large and small, which he has overcome. If the investigator is to aid the practicing physician, the work they do must be integrated, dedicated to the truth, and applied toward preventing disease and maintaining health. In the present-day practice of medicine therapy, the nature of which little is known, is often applied; yet something may happen and relief may occur, temporary perhaps but relief nevertheless. Of that something that happens even less is known than about the therapy that is applied. My definition of health, as it might fit into a working concept, is the accurate, harmonious, and constant integration of all the necessary biochemical factors in the body. The vitamin balance, the endocrine balance, the electrolyte balance, the control of the body temperature, the maintenance of the blood glucose level, and the supply of oxygen to the cells are a few of the important factors. A derangement of any of these or of any other biochemical system disturbs the harmony of the cells and results in ill health. Ill health may come from trauma or infection or even from the disturbance of mental processes; many physiological phenomena are associated with emotions. For example, anger may cause the blood pressure to rise, sadness may bring excessive lacrimation, and excitement may result in insensitivity to pain; therefore, the state of mind alters the body functions. Mind and body work together continuously and are mutually dependent. Health is a normal outcome of such a harmonious relationship.

The success of preventive medicine depends on early perception of any source of disharmony. By the time the physical signs characteristic of disease are observed, the tissues have been badly damaged. Hence, the physician should attempt to develop insight into the biochemical action within the cell so that he will have knowledge of living processes. Because the mechanism of action is unknown, he must not fall into the error of thinking it is unknowable. To initiate this concept is a formidable undertaking, but it is one that must be undertaken.

The problems first to be considered are what causes chemical deterioration and how can such deterioration be predicted chemically and be chemically rectified. At the present time many physicians tell their patients, in effect, "to be their age, to take it easy, to slow down, and to avoid the pace that kills." In fact, they advise them how to live with their strokes, with their coronary accidents, with their emotional depressions, and with their pains and agonies, and how to grow old gracefully. It would mean a great deal if middle-life deterioration could be predicted in advance and reversed before serious symptoms occur. If the physician could avoid putting patients in beds and could allow them to work, and if further chemical deterioration could be prevented and the deterioration already present could be reversed, hospitalization could be cut down enormously and many young executives, technical men, and laborers could be kept in production for many years to come. Heart disease and strokes are not sudden causes of death. They occur as a result of years of chemical deficiency. To prevent disaster, a chemical audit, a diagnosis of chemical deficiency, and a corrective nutritional and chemical regimen are needed.

In 1928 studies were being made from the point of view that a human being is a product of the air he breathes, the water he drinks, and the food he eats; day after day, year after year, the tissues of the human body are replaced by intricate combinations of oxygen, water, and food. Today this is a medical axiom, and physicians have gone a long way toward showing that disease is chemical and chemically correctable.

DEFICIENCY DISEASES

After eight years of studying in the North, my associates and I initiated a study of deficiency diseases in an area in which they were endemic. At first we studied only adults with nutritive failure, but we soon learned that the children ate inadequate diets similar to those eaten by adults and that deficiency disease lesions, which waxed and waned with the seasons, developed in these children. At this time we observed that clinical evidence of deficiency diseases in adults was much commoner in women than in men, particularly in women of child bearing age. Our studies showed that the mother's diet often was inadequate during pregnancy and lactation, and frequently her supply of breast milk was not sufficient for the infant's needs. The infants were given foods from the family table, usually corn bread, syrup, biscuits, and grits, but few ever received orange juice or cod liver oil. These children were puny and fractious. They cried a great deal, were restless, and seemed too tired to play. A remarkable difference was observed between the personalities of these children with nutritive failure and those of normal children. Unlike normal children, they were apathetic and lacked the usual childhood interests.

Read before the General Scientific Meeting at the 102nd Annual Session of the American Medical Association, New York, June 1, 1953.

From the Department of Nutrition and Metabolism, Northwestern University Medical School, Chicago, and the Nutrition Clinic, Hillman Hospital, Birmingham, Ala.

The scientific evidence on which this report is based was produced by the author and more than 100 associates. The investigations described here were initiated 25 years ago and have been aided by many philanthropic persons, foundations, and corporations.

The researches on milk in the recent past have been supported by the National Dairy Products Corporation, the researches on rehabilitation by means of hormones by the Clayton Foundation for Research, and the researches on certain aspects of geriatrics by Hoffmann-La Roche, Inc.

Vitamin Supplementation.—We decided to ascertain what would happen when we administered synthetic vitamin supplements consisting of nicotinamide, thiamine, and riboflavin to these children. We soon learned that the lesions of pellagra, beriberi, and riboflavin deficiency disappeared following the administration of sufficient doses of these vitamins. The children's appetites tended to increase, and they gained in body weight. Unless their diets improved, however, the gain soon leveled off. It was obvious that the synthetic vitamins did not compensate for the deficiency of the other nutrients in their generally inadequate diets.[1]

By this time it was apparent that we should study the effect of chronic nutritive failure on the growth progress of children. During the past 15 years the growth patterns of over 3,000 children with and without nutritive failure have been investigated. In association with Dr. Samuel Dreizen, Miss Catherine Currie, and Miss Jo Gilley, we selected and repeatedly studied 2,000 children without evidence of nutritive failure and 600 children with chronic nutritive failure who had never received vitamin or other dietary supplementation.[2] All the children were seen frequently in the Nutrition Clinic, and on each visit height and weight measurements were made. The ages of these children ranged from 3 years to 16 years. The growth patterns were evaluated independently by the Wetzel grid technique and by a compilation of height and weight curves.

Analyses showed that, in children with nutritive failure, a substantial lag in height and in weight was present by the third year of life. Thereafter, the weight lag increased progressively in both boys and girls with nutritive failure. The height lag in boys with nutritive failure became progressively greater, while that of the girls remained fairly constant. The maximum mean isodevelopmental level [3] reached by boys with nutritive failure was 140 at 15 years 6 months. This level was reached by boys without nutritive failure 2 years 3 months earlier, when they were only 13 years 3 months old. The maximum mean isodevelopmental level reached by girls with nutritive failure was 130 at 15 years 3 months. This level was reached by girls without nutritive failure 2 years 6 months earlier, when they were only 12 years 9 months old. By the time the boys and girls with nutritive failure began to approach physical maturity, they had undergone a mean growth lag of over two years.

Milk Solid Supplementation.—The extent to which this retardation is reversible by means of dietary supplementation with milk solids has been investigated with regard both to over-all body size and to skeletal maturity. Eighty-two children with nutritive failure were paired by sex, skeletal age, grid position, and prevailing phase of growth. These children ranged in age from 4 years to 15 years. One child in each pair received a dietary supplement of milk solids equivalent in protein value to one quart of milk daily, six days per week, for a period of 20 months. No supplementation was offered the other child of each pair. By using the Wetzel grid technique, we found that 73% of the children receiving the supplement made more than one isodevelopmental level per month, as compared with only 39% of those in the control group (those not receiving the supplement). Improvement in physique was observed in 34% of the test subjects and in only 15% of the controls. Speed of growth was increased in 54% of the test subjects and in only 7% of the controls. Improvement in growth quality (indicated by improvement in physique plus an increase in speed of growth) was observed in 27% of the test subjects but in none of the controls.

In association with Dr. Dreizen, Dr. Richard Snodgrasse, Dr. George S. Parker, and Miss Currie, we used similar criteria in selecting an additional 41 pairs of children. These children ranged in age from 1 year to 10½ years. The children in the test group were given milk solids equivalent in protein value to three quarts of milk a week for a period of 40 months, while the control group did not receive a dietary supplement of any kind.[4] Although the test subjects in this group received the same total amount of milk solids as those in the first group, the milk solids were given to the second group over a period of time twice as long, so that the average weekly amount was only half of that given to the first group. At the end of the 40 month period no differences between the test and control groups were measurable either by the Wetzel grid technique or by the skeletal maturation techniques, thus showing that we had arbitrarily selected an average weekly amount of milk that was too small to produce measurable changes.

In 19 of the test subjects the amount of milk solids was increased to the equivalent of 12 quarts of milk weekly (2 quarts a day, six days a week). This was four times the average weekly amount given during the 40 month period and twice the average weekly amount given during the 20 month period. The remaining test subjects continued to receive the three quart weekly level. To facilitate giving 12 quarts of milk weekly and to make it possible for the entire daily amount to be given in one feeding, one-half the milk solids was reconstituted in as small an amount of water as possible and frozen to the consistency of ice cream. One-half ounce of sugar and a few lemon drop chips were added for flavor and palatability. The other half of the milk solids was reconstituted to either a pint or half-pint volume (depending on the age of the child) and fed with the ice cream. This supplement was fed for a period of six months. At the end of the six month period the rate of skeletal maturation in the test subjects had increased by 80%. The increase in skeletal maturation of boys receiving the 12 quart weekly level exceeded that of their paired controls by 93% and exceeded that of boys receiving the 3 quart weekly level by 65%. The increase in skeletal maturation of girls receiving the 12 quart weekly level exceeded that of their paired controls by 90% and exceeded that of girls receiving the 3 quart weekly level by 90%. In 17 of the 19 test subjects (89%) on the equivalent of 12 quarts of milk weekly, the rate of skeletal maturation in the most advanced centers increased, thereby reducing the lag between their actual and genetically limited growth rate. This occurred in only 45% of the children receiving the three quart weekly level and in 46% of the controls. Acceleration in the rate of maturation of the least advanced bone center was shown by 58% of the children receiving the 12 quart weekly level and in only 23% and 27%, respectively, of those receiving the 3 quart weekly level and those serving as controls.

[3] By the Wetzel grid technique, isodevelopmental level is a measure of the body surface area based on the height and weight of the child.

[4] Spies, T. D., and others: Unpublished data.

Despite differences in nutritional requirements at different ages, there appears to be no relationship between chronological age and the degree of increase in bone maturation. From this study it appears that the removal of deficiencies of skeletal maturation in the child, regardless of age, is dependent primarily on the adequacy of the level of supplementation, thus the retarding effect of prolonged nutritive failure is reversed promptly if the nutrients in the dietary supplement are supplied in sufficient amounts to overcome the accumulated deficiencies. Brief summaries on the following two patients are illustrative:

Case 1.—This girl, the youngest of five children, was born at a time when her family's economic status was at its lowest. Her father, who had worked as either a miner or a sharecropper since the age of 13 years, was in a mining accident two years prior to the child's birth and was never again able to work. From the time of his accident until his death eight years later, the family was dependent on charity. They received from $8.00 to $18.00 per month. Their diet consisted of dried beans, corn bread, biscuits, and occasionally a small amount of fat pork. During this interval pellagra developed in the mother and four of the children, and they were treated by us. When we first examined the girl, she was nervous, cross, and apprehensive. She cried frequently, did not sleep well, and complained of muscular cramps, headaches, and stomach-ache. She had bilateral cheilosis. She was a small child who looked like a wizened old lady. In school she had not done well; she had repeated each semester at least once and was only in the third grade at 12 years of age. She enjoyed playing with the children in her own grade, who were about four years younger than she.

The grid analysis for this girl is seen in figure 1. When she was 7 years 10 months of age, she had clinical pellagra and had an extremely poor physique (channel B-4 on the grid). She was progressing on a very slow age schedule. Her developmental age (using the 67% auxodrome, or age schedule, as the standard of reference) was 5 years 7 months, showing a growth lag of 2 years 3 months. When she was given nicotinic acid, the lesions of pellagra disappeared and she felt better than she had prior to this therapy. Her diet remained inadequate, however, and at the end of a year she was retarded 4 years 6 months in over-all body size. This indicated that, although the nicotinic acid was specific for nicotinic acid deficiency, her growth and development could not improve until her dietary intake improved. Her diet then became somewhat more adequate, and by the time she was 11 years 6 months of age, her growth lag was 2 years 10 months. We decided to put her on supplementary feedings of reconstituted dry milk solids, and she was given the equivalent in protein value of one quart of milk per day, six days a week, for a period of 20 months. No further improvement in physique occurred, but her speed of development continued to increase slowly. In the 20 month period her retardation in growth was reduced by five months. During the time she received the milk supplement, she was cheerful, friendly, and pleasant. Her mother and all other observers noted that she had more energy, slept better, and was less nervous than she ever had been. Her teachers saw a definite change in her ability to concentrate on her studies and to retain information that she acquired. They noted also that she had a great deal more energy, and for the first time she would participate in group activities. From that time on, she had no failing grades and was delighted and proud of herself when she passed to the fourth grade.

Case 2.—The patient's family, as that of case 1, was in a state of nutritive failure from the time the members were first examined in our clinic. The patient, 1 of 11 children, was breast-fed until she was 18 months of age and had no supplements such as orange juice or cod liver oil. She was given butter bean soup "to start real eating." As a small girl, she was easily fatigued and had frequent headaches and severe cramps in her legs. Most of the time she fretted and cried, and frequently she had bilateral cheilosis. At best, her two meals a day included butter beans, salt pork, bread, and molasses. On several occasions treatment with riboflavin was followed by relief of the cheilosis. When she was 12 years of age, a supplement of dry milk solids reconstituted in water was initiated. Promptly she began to grow taller and to fill out. After she had received the milk supplement for 14 months, her body changed from that of a scrawny, thin girl to that of an adolescent. Her energy and appetite increased, and she had no lesions of riboflavin deficiency. When the therapy with a supplement was discontinued, the cheilosis returned. When she was treated again, the lesions disappeared.

The grid analysis from case 2 is shown in figure 1. As can be seen, when she first was seen in the clinic, her physique was fair (channel B-2) and she was progressing on a very slow age schedule (98% auxodrome). Using the 67% auxodrome as the standard of reference, she was retarded 1 year 6 months and her developmental age was 6 years 6 months. Further loss of physique occurred together with progressively greater retardation, until at the age of 10 years 4 months she was 2 years 8 months retarded. At that time she began to progress, and her speed of development (only one incident of growth failure, occurring at 11 years 4 months) increased, until at the age of 12 years she was retarded only 16 months. At this time she was placed on the dietary supplement of dry milk solids equivalent in protein value to one quart of milk per day, six days a week, for a period of 14 months. Throughout the period of supplementation, she continued to improve with less fluctuation and continued to increase her speed of growth. At the end of the period of supplementation she had a fair to good physique and was retarded only seven months. Her retardation was reduced by nine months in the 14 months of supplementary feeding. The differences in maturity, as indicated by secondary sex characteristics, are clearly evident in the photographs (fig. 1) of the two girls.

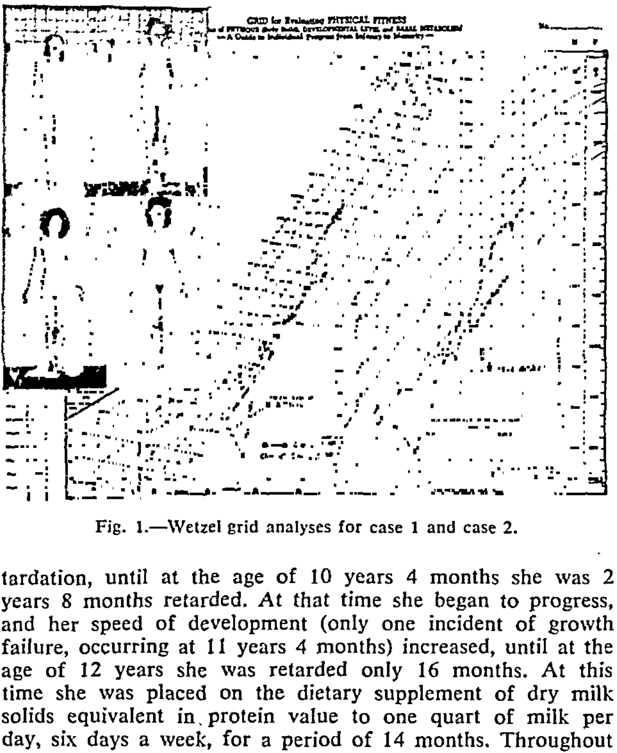

Fig. 1.—Wetzel grid analyses for case 1 and case 2.

Solid Food Supplementation.—Nutritionally speaking, a 9-month-old baby has had 18 months of nutrition, that is, including the 9 month prenatal period. With birth the whole question of adjustment arises. How soon the baby can take solid foods is an important matter. The revolutionary schedule of giving solid foods early is one of recent vintage. For too long this type of food was not offered to the infant, since it was considered that a baby's stomach was not big enough to contain sufficient food to provide adequate nourishment and that he should have frequent feedings in liquid form. Recently we began studying the introduction of food other than milk as early as the second day of life. For a special long-term study we selected 24 children, ranging in age from 2 months to 2½ years, and placed them on supplementary feedings of Swift's meats for babies. Children under 1 year of age arbitrarily are given strained food, and those over 1 year of age are given chopped foods. Each subject receiving the meats has accepted this supplementation enthusiastically and appears to be growing at a faster and more regular rate than his control.

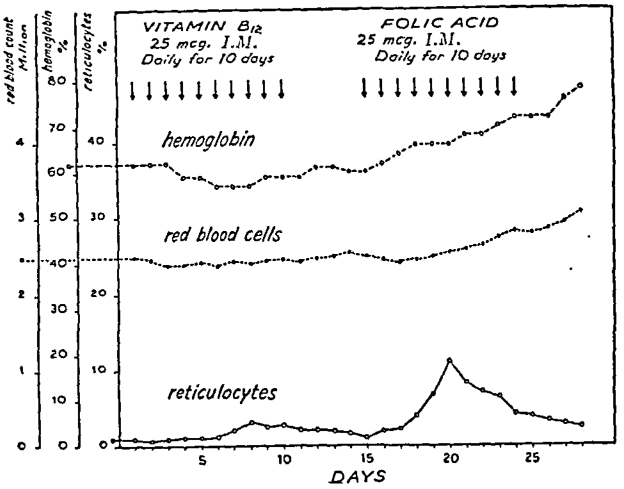

Fig. 2.—Comparative evaluation of vitamin B_{12} and folic acid per unit of weight in a patient with macrocytic anemia of pregnancy.

Rickets: In our clinic it is not uncommon to see an obvious case of rickets. It always has interested us that severe clinical rickets occurs not only in children who lack vitamin D or sunlight exposure but also in some children who grow rapidly. This rapid growth has a great deal to do with the clinical evidence of rickets. Clinical rickets, as we see it in Alabama, occurs chiefly among the Negro children who sleep a great deal during the day. Those who are out in the sun show no evidence of rickets. Occasionally one sees white children with rickets, but usually they are children who are growing very rapidly. The incidence of rickets is limited almost entirely to the temperate zones. The characteristic deformities are not so common now as formerly, but we still see the milder form. In some ways the mild form is more serious, since it is more difficult to recognize and, therefore, may escape treatment. It is well known that the pathogenesis of rickets lies in the condition of the calcium and the phosphorus in the blood serum and that in rickets the concentration of phosphatase in the serum is increased. Human milk is by no means antirachitic. To prevent rickets, vitamin D should be administered. Vitamin D produces its regulatory effect on the content of calcium and phosphorus in the fluids of the body. With satisfactory treatment the bony deformities of rickets gradually disappear, the bones acquire an increased degree of rigidity, and the muscles seem to improve.

Anemia: A medical mistake being made at the present time is failure to administer iron in cases of iron deficiency anemia. When the physician finds that the patient cannot tolerate large doses of iron because of the resulting gastritis or diarrhea, too often he gives the patient no iron at all. Smaller doses would be well tolerated and, if given over a long enough period of time, would produce satisfactory responses.

Ascorbic acid, folic acid, and vitamin B_{12} are nutrients that are essential for health and well-being. Vitamin B_{12} is essential for the integrity of the nervous system and the bone marrow. Folic acid is essential for relieving the macrocytic anemia of pregnancy and of infancy and is most useful in the treatment of persons with endemic sprue or nutritional macrocytic anemia. Figures 2 and 3 indicate our recent experiences and observations with these materials. The use of ascorbic acid in the treatment of scurvy is extremely well known. It, like pantothenic acid, seems to be essential for the integrity of the adrenal glands.

Obesity: The obese patient presents a medical problem common to most practicing physicians. Patients offer many excuses for overeating, but, if they will consider their problem realistically, they are inclined to agree with the diagnosis of obesity. What they really do not like about the diagnosis is the implication that they are "eating themselves fat." Many reducing diets are unbalanced and actually inadequate in a number of respects. Nonfat dry milk solids are being used more and more as a basis for reducing diets. Because they are an excellent source of protein and calcium, they make an important contribution to a reducing diet. A nonfat dry milk that we have found acceptable and useful is a product that has vitamins and minerals added in the following amounts per quart:

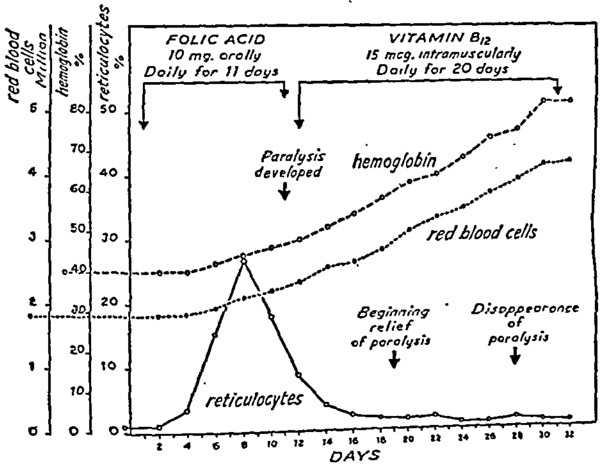

Fig. 3.—Development of symptoms of acute combined degeneration of the spinal cord in patient with pernicious anemia who was receiving folic acid therapy; the symptoms disappeared with vitamin B_{12} therapy.

Vitamin A	4,000 USP units
Vitamin D	400 USP units
Vitamin B_1	1 mg.
Vitamin B_2 (riboflavin)	2 mg.
Niacin	10 mg.
Iron	10 mg.
Iodine[5]	0.10 mg.

Physicians are beginning to understand that overeating often is a manifestation of a fundamental disturbance that is primarily psychological or emotional in nature. Leonard Williams has said that obesity is divided into three stages known, respectively, as the enviable, the comical, and the pitiful. This is a false estimate of values. Obesity is always tragic. A list of its hazards is terrifying.

---

[5] Iodine may be added in the Midwest because of the incidence of endemic goiter.

DISEASES IN OLD AGE

Every investigation of nutritive failure that we have made in the past 20 years has indicated the predominance of mixed, rather than single, deficiencies of elements essential for life. The margin of safety against certain deficiency diseases is narrow rather than broad. Figure 4 shows the age incidence of deficiency diseases in males and females. Note that during the child bearing period of life many more women are affected with clinical evidence of deficiency disease. After this period is over, this difference gradually disappears, and after the age of 70, the age incidence of dietary deficiency diseases seems remarkably similar in men and women. For a quarter of a century I have had a deep interest in trying to understand the underlying chemical changes that precede senescence. A long time ago we became impressed with the extreme variation in response to the wear and tear of life. It seemed very striking that some persons weathered the years from 45 to 70 in such a way as to appear to be still as biologically, physically, and mentally active as they were at the age of 40 and seemed destined to live a number of years. The true killers such as cerebral accidents, coronary disease, and cancer of the stomach, which strike so often between 45 and 70 years of age, seem less likely to occur after the age of 70

In this report it is not possible to mention all the combinations of vitamin and mineral deficiencies that might occur. As a part of our over-all concept, we consider that the nutrients essential to the growth and development of infants and children are necessary for the maintenance of vigor and strength of the person who has matured. We have chosen a number of older persons with well-recognized chronic syndromes and demonstrated that their health can be so improved that they can be returned to gainful occupations. How much better it would be if susceptibility tests were available that would tell in advance which persons should be observed and for what, so that truly scientific preventive medicine could be done. When that day comes, physicians shall be busy preventing disease rather than treating patients in late stages of disease.

Leukemia.—A number of substances are directed toward destroying existing leukemic tissue and toward preventing the multiplication of leukemic cells in persons with leukemia and lymphosarcoma. None of these substances is a positive cure for the disease. We have been concerned especially with the effect of corticotropin (ACTH) and cortisone and have seen some interesting results, particularly in cases where the bone marrow has been heavily infiltrated. The brief case history that follows indicates what can be accomplished in selected cases:

Case 3.—A 53-year-old white woman was brought to the clinic because of loss of weight and strength, a breaking out of the skin, and swellings in her neck. She had been in good health until a few years before admission, when she noticed that she lost her strength insidiously and could not do her housework as well as usual. She eventually could not do her housework at all; soon a rash appeared all over the body. Swellings appeared under her arms and in her neck. Her white blood cell count was 78,000, and at this time she was given x-ray therapy. The white blood cell count was reduced to 14,000, and she felt somewhat better. After this, however, she promptly suffered a relapse, and x-ray therapy was found to be of no value. Six months after she had received no therapy whatsoever, she returned to the clinic. She said that she "just hardly could go." One hundred milligrams of pituitary corticotropin (Armour) was administered intramuscularly in divided doses every six hours. Promptly she began to feel better, her leukocyte count fell from 60,000 to 13,850, and hemoglobin rose from 36% (5.6 gm.) to 79% (12.2 gm.). Her weight increased 10 lb. (4.5 kg.), and she gained greatly in strength: After being treated for a month, she felt very well. She had started to do her own housework again. Therapy was discontinued at that time.

While examination reveals some swelling of the lymph nodes and blood smears show characteristic leukemia, the patient in case 3 has been free of symptoms for over three years. We do not understand the precise chemistry of what has happened in this patient or in others who have improved, nor do we understand the difference between the patients that improve and those in whom a satisfactory response does not occur. Perhaps any form of leukemia is not a single disease but is the result of a variety of causes. At any rate some vital reaction occurs.

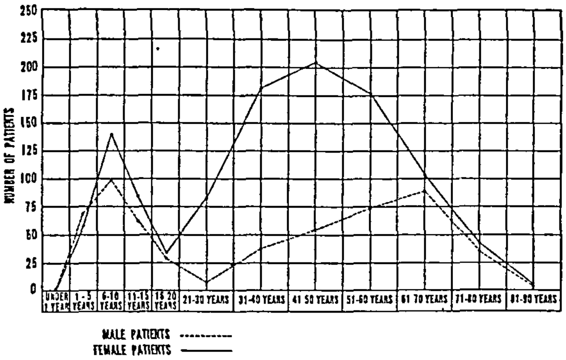

Fig. 4.—Age incidence of patients with deficiency diseases in 1944.

Since we have seen no patient who has returned entirely to normal, we must conclude that there is no known method of treatment that is a cure for leukemia.

Chemical Disturbances.—In our approach to the chemical disturbances that may affect persons of "advanced maturity," we keep in mind that these disturbances are responses of living tissues to abnormal chemical situations. We know that tumors existed in prehistoric animals, and in our study of the problem we have chosen many avenues of approach.

Several years ago Dr. Rolf Ladisch submitted to me a hypothesis that incorporated the concept that the quinones from certain beetles might be carcinogenic under certain circumstances. Dr. Ladisch, Dr. Dreizen, and I have worked with materials from the thoracic and abdominal glands of the Tribolium confusum and Tribolium castaneum species of beetles, insect infestants of common cereals, in order to observe their effect on living matter. From the secretions of these glands we have obtained and used three quinones with chemical structures resembling carcinogenic agents. To 36 rats of the Long-Evans strain, these materials were given in varying doses in the food, in the water, or by subcutaneous injection. For a long period of time there were no noticeable effects on the growth rate, health, or physical appearance of the rats so treated. Eventually 10 of the 36 rats in the experimental group and 1 of the 9 litter mate controls (not given the test material) showed a progressive decline in weight, extending from four to six weeks prior to death. Gross and microscopic evidence of tumor formation was found in each of these animals. The structure of these tumors can be seen in figure 5. From these preliminary observations it would seem that the quinones isolated from the glandular secretion of the beetles probably provoked tumor formation and that the tumors are of the type described by Gillman and Gillman in their classic work on experimentally produced lymphomata in rats.[6] Many questions arise that eventually must be answered. Could these masses be transplanted? Why did tumors not develop in the majority of rats? Is there any practical importance to these observations, or do they merely ascertain the information that the administration of the quinones may be followed by tumor formation? At least these preliminary observations fit into our over-all concept that proper chemical environment is of utmost importance and is essential for the health of all living tissue.

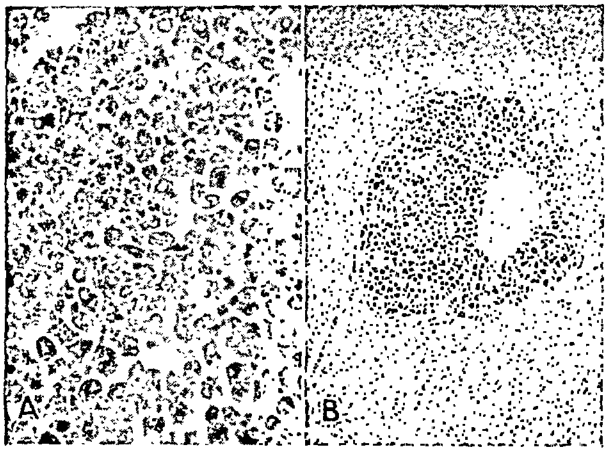

Fig. 5.—Tumors found in rats injected with carcinogenic quinones from beetles. *A*, abdominal mass (× 167), and *B*, liver showing normal liver pattern surrounding a well-demarcated cluster of abnormal cells (× 30).

Psychotic Reactions: For many years it has been known that pellagrins often manifest psychotic changes, but the association of psychoneurotic symptoms with subclinical and mild pellagra was not appreciated until it was pointed out that these patients were frequently disgnosed as neurastheniacs. We learned that these symptoms had certain distinctive characteristics, that they were significant in making an early diagnosis of the disease, and that such symptoms disappeared dramatically following nicotinic acid therapy. In addition to the elementary syndrome associated with it, there were the general symptoms of central nervous system involvement characterized by weakness, increased fatigability, sleeplessness, and headaches.

As a part of the elementary psychosensory disturbance, the patients described conditions as making them feel "uneasy" or as bothering or hurting them. They could not tolerate bright colors or bright lights, and noises such as the slamming of a door or the screaming of a child produced a great emotional shock, with the result that they felt "jerky and shaky." As the condition became severer, these noises became unbearable. They found that odors that had never bothered them before were so disagreeable that they caused nausea and vomiting. Several patients who had enjoyed cooking said that the orders become so unpleasant that they caused distress and agony. Tastes changed so that they disliked foods intensely. These patients were tense, irritable, and, as they said, "on edge." Prominent complaints were dizziness, a feeling of uncertainty, and difficulty in maintaining balance. They complained of feeling "restless on the inside" and of being much more excitable and sensitive than they were before their illness. Their emotional reactions were directed toward a depressive response; they had sad, gloomy moods associated with constant apprehension. They seemed constantly to be engaged in a struggle between a desire to rest and a feeling of restlessness. The breakdown of personality was striking: persons previously strong, courageous, and enduring became wary and apprehensive.

Pernicious Anemia: We have known for some time that a rare patient with pernicious anemia in relapse will respond to as little as 5 mcg. of vitamin B_{12} administered orally, whereas others will respond only when a dose of several milligrams is given. For many years we have been interested in the fact that patients with pernicious anemia lack a certain enzyme in their gastric juice. There is much current interest in intrinsic factor preparations, which act as activators of vitamin B_{12}, making it possible to decrease greatly the oral dose of this vitamin. Several pharmaceutical concerns have produced active intrinsic factor preparations that we have found will potentiate the effect of vitamin B_{12} administered by mouth to patients with pernicious anemia in relapse. The response of such a patient to this therapy is illustrated in the following case history:

Case 4.—A 72-year-old machinist was brought to the clinic in late 1948 complaining of weakness, fatigability, and occasional soreness of the mouth and tongue. Fatigability and loss of strength began about three years previously. He felt tired all the time and was content to just sit all day. The soreness of his mouth and tongue began two years previously, recurred intermittently, and varied in severity; at times he had difficulty in even drinking water. A sensation of numbness of his feet and of having pads of cotton under his toes had been present for a year and a half. Numbness of his fingers had been present for three weeks. For several weeks he had noticed dyspnea on exertion. A year and a half before he was admitted, he consulted a physician who told him that he had anemia bordering on pellagra and gave him an injection every other day for about a year. In the patient's opinion this therapy gave him little, if any, relief. Because his work required a high degree of skill in using his hands, he had not been able to work regularly.

Physical examination showed generalized pallor. The scleras and conjunctivas were pale, and there was slight icterus of the scleras. His tongue was slightly thickened, and there were scattered denuded papillae at the tip and along the margins. The findings of the neurological examination were within normal limits. An oral glucose tolerance test showed a normal curve. Repeated gastric analyses showed no free hydrochloric acid in the gastric juice even after histamine stimulation. The stools were normal. There was megaloblastic arrest of the bone marrow, characteristic of pernicious anemia in relapse.

[6] Gillman,; J. Gillman, T.; Gilbert, C., and Spence, I.: Lymphomata (Including Hodgin's-Like Sarcomata): Their Experimental Production: A Study of Their Pathogenesis and Etiology and a Comparison with Corresponding Tumours in Man, Clin. Proc. 8: 222 (Dec.) 1949; The Pathogenesis of Experimentally Produced Lymphomata in Rats (Including Hodgkin's-Like Sarcoma), Cancer 5: 792 (July) 1952.

The initial peripheral blood values were red blood cells 2,870,000, hemoglobin 72% (11.1 gm.), and reticulocytes 0.4%.

He was given a single 50 mcg. oral dose of vitamin B_{12}. His blood values and clinical condition remained essentially unchanged for a month. Then he was given a single 450 mcg. oral dose of vitamin B_{12}. Four and five days later his reticulocyte count was 4.8% and 5.0%, respectively, and subsequently there was a slight increase in red blood cells and in hemoglobin. His fatigue was relieved slightly, he felt better in general, and his color improved. Neurological examination at this time showed slight hyperesthesia of the distal third of the forearms, of the hands, and of the fingers, slightly severer in the fingers. There was slight hyperesthesia from just above the knees to the ankles. There was a tingling sensation of the legs and slight tenderness of the heels.

He was given a single 25 mcg. intramuscular injection of vitamin B_{12}. Four days later he volunteered that there was less tingling of his fingers and numbness of his toes and that he no longer had any burning sensation of his tongue. By the following day all the redness of his tongue had disappeared, and he said that he had more energy and that he "felt like doing something." The numbness of his feet and the tingling of his fingers continued to subside. Nine days after the first injection of vitamin B_{12}, he was given a second injection of 25 mcg. intramuscularly. Within the next three weeks the symptoms of nerve involvement, all the soreness of his mouth and tongue, and the dyspnea disappeared gradually. At the end of this time his blood values were red blood cells 4,210,000; hemoglobin 83% (12.7 gm.); and reticulocytes 1.8%. A month later he went back to work full time.

In the following four years he had intermittent therapy with vitamin B_{12}. In March, 1953, he complained of fatigue, tingling and numbness in his fingers, and a burning sensation of his tongue, which was moderately reddened on both upper and under surfaces. His blood values were erythrocytes 3,240,000; hemoglobin 73% (11.3 gm.); and reticulocytes 2.8%. He was given four tablets of vitamin B_{12} and an intrinsic factor concentrate daily for 10 days. On the fourth day of treatment he felt less fatigued and the soreness of his mouth decreased. The tingling and numbness of his fingers decreased on the sixth day of treatment. By the seventh day he said that he felt "like a 2-year-old." By this time all the redness and soreness of his tongue had disappeared, and by the ninth day he no longer had any sensation of numbness and tingling of his fingers. On the seventh day of therapy his reticulocyte count was 10.8%. On the 10th day his red blood cell count was 3,750,000 and his hemoglobin 83% (12.8 gm.). Three weeks after this therapy was initiated, his red blood cell count was 4,070,000 and his hemoglobin 72% (11.1 gm.).

After the first period of therapy in 1948, he began working regularly. His work requires a high degree of skill in the use of his hands. He measures with a micrometer, and measurements must be accurate to one-thousandth of an inch. He says, "I feel a thousand times better than I did when I first came to the clinic, and I am happy to work again."

Studies of this case and many others show that, in order to determine the intrinsic factor activity of any preparation, one must first do carefully controlled tests showing that the oral administration of the amount of vitamin B_{12} in the preparation cannot, in itself, produce any detectable effect. Then one must show that the administration of the same amount or less of vitamin B_{12} and a potent intrinsic factor concentrate is effective under the same conditions (fig. 6).[7] After years of testing, I prefer to conduct the tests using 5 mcg. of vitamin B_{12} per day, although we often use 10 or 15 mcg., or even more. The larger amounts are less satisfactory because they require more careful and definite control. We have found that patients who do not respond to 5 mcg. of vitamin B_{12} orally have a maximum hemopoietic and clinical response when as little as 1 mg. of the purest concentrate of intrinsic factor is administered along with 5 mcg. of vitamin B_{12}. We have given concentrated intrinsic factor and vitamin B_{12} as long as two hours apart, and a definite hemopoietic and clinical response has followed, indicating that the intrinsic factor and vitamin B_{12} must interact in the intestinal tract. The purest preparations of intrinsic factor concentrate show definite evidence of being a protein. Obviously such studies show that the day of practical oral therapy with vitamin B_{12} is near at hand for the physician who chooses to use it for selected patients.

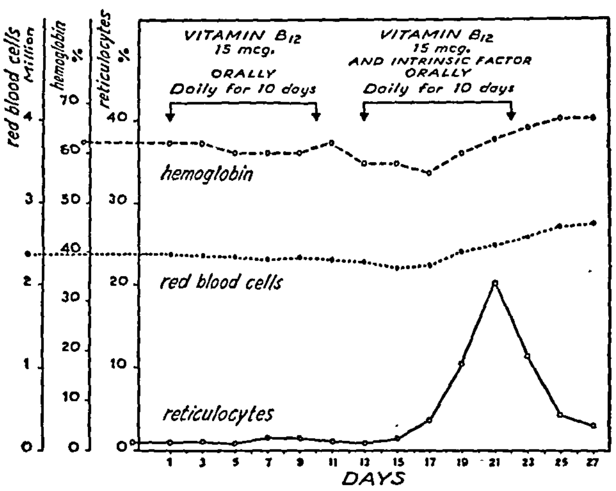

Fig. 6.—Hemopoietic response of patient with pernicious anemia to the oral administration of vitamin B_{12} alone and with intrinsic factor.

In many cases vitamin B_{12}, like some of the other vitamins, has a special effect on appetite. This appetite stimulating property is not precisely related to the increase of red blood cells or hemoglobin in the blood. When patients with pernicious anemia or tropical sprue in relapse are given transfusions and their blood values increase, they do not get the remarkable increase in strength, vigor, and appetite as is induced after the administration of large amounts of vitamin B_{12} or folic acid (fig. 7 and 8). In studying selected patients with pernicious anemia we have learned that when their blood values increase to normal following repeated transfusions, they feel fine; if they are given injections of sterile sodium

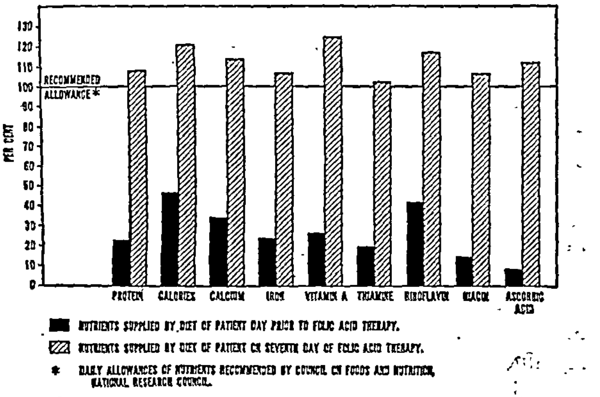

Fig. 7.—Nutrients supplied by diet of patient with pernicious anemia before and after folic acid therapy.

[7] Spies, T. D., and others: Antianemic Properties of Reaction Products of Vitamin B_{12} and the Intrinsic Factor, J. A. M. A. 151: 1264 (April 11) 1953.

chloride, they do not get an increased sense of well-being; when vitamin B_{12} is administered without their knowing they are getting different injections, they do get a definite "lift" and feel much better.

Vitamin B_{12}, like folic acid, thiamine, nicotinamide, riboflavin, and ascorbic acid, is singularly free from unpleasant side-effects. It has a most important place in practical therapeutics. The evidence of 25 years of work shows a wide variation in the individual needs of patients with pernicious anemia. The value of vitamin B_{12} as a growth factor for children cannot be regarded as established. One cannot, by physical examination or studies of the blood or bone marrow, tell before therapy whether or not a person has a deficiency of folic acid or vitamin B_{12}. Folic acid has a special relationship to pregnancy; vitamin B_{12} has a special relationship to the nervous system. Vitamin B_{12} itself was isolated during a search of liver extracts for the material that produces a remission in pernicious anemia. There is a plentiful and cheap supply, and the material has become available for general use.

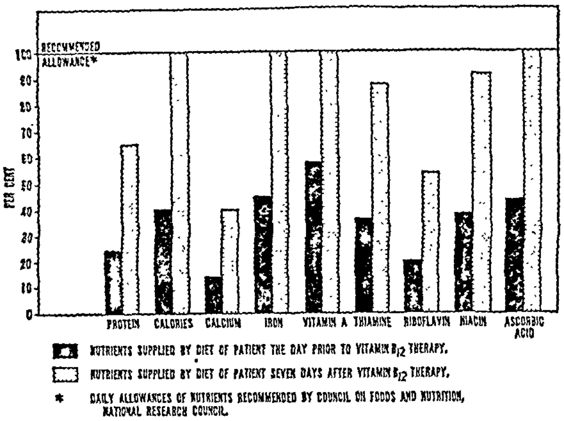

Fig. 8.—Nutrients supplied by diet of patient with tropical sprue before and after vitamin B_{12} therapy.

Megaloblastic Anemia: In the treatment of the average case of megaloblastic anemia of sprue, of infancy or of pregnancy, vitamin B_{12} is not as efficient as folic acid. In fact vitamin B_{12} does not induce a hemopoietic response in the usual case of macrocytic anemia of pregnancy or of infancy. It is clear that many patients need both folic acid and vitamin B_{12}. Folic acid is composed of pteroic acid and glutamic acid, and, when these materials are administered separately or together, the body cannot fabricate them to make folic acid, thus showing that folic acid is a true vitamin and must be prefabricated outside of the body. When given in massive doses, thymine (5-methyluracil) produces a hemopoietic and clinical response similar to folic acid. The folic acid content of the following foods is high: fresh, dark green, leafy vegetables; liver; cauliflower; kidney; beef; veal; and dry wheat breakfast cereals. The following foods are low in folic acid content: root vegetables; tomatoes; bananas; milk; cheese; pork; ham; lamb; rice, corn meal; and sweet potatoes.

Arthritis: In the four years that have elapsed since corticotropin and cortisone were first used as therapeutic agents, so much has been written on them that it often must be difficult for the practicing physician to evaluate their usefulness in the day-to-day practice of medicine. In order to do this, he first must realize that the adrenal cortex is vital to daily living in protecting the human being against many changes in his environment. Although the proper use of these hormones requires a great deal of scientific information, it is desirable that the practicing physician use them. By judicious use, they have been found to be invaluable therapeutic agents, as is illustrated in the following case history:

Case 5.—A 40-year-old coal-loading machine operator was admitted to the clinic complaining of arthritis of nine years' duration. Until nine years previously he considered his health to have been unusually good; then he twisted his left shoulder while operating a coal-loading machine. A roentgenogram of this shoulder revealed nothing abnormal at that time. His shoulder was taped, and he was given heat therapy, but the pain was so severe that he was given sedatives to relieve it. After five or six days the pain subsided sufficiently to enable him to return to work, but it was not relieved completely, About a week later intense pain suddenly developed in the right groin, and he was admitted to a hospital and given injections to relieve the pain. After nine days in the hospital he was discharged. Since then, the pain had "jumped" from one joint to another and by this time had involved almost every joint in his body. Every two or three weeks he had an acute attack of pain, and, when his joints became swollen, red, and hot, the pain was so intense that he was unable to work for four or five days. Five years prior to his admission he gave up working in the mines, and since then he had done odd jobs when he felt able to work. During the nine years of his illness he had had many kinds of therapy. Hot mineral baths had given him more relief than anything else he had tried.

Physical examination showed a well-developed, well-nourished man with good color. His finger joints were slightly enlarged and tender. There was slight atrophy of the intrinsic muscles of the dorsum of the hands. The elbows were slightly enlarged. The right shoulder was tender and slightly swollen. There was diffuse swelling and slight tenderness of the right ankle, and there was tenderness through the distal part of the right foot. The left ankle was slightly swollen but not tender. Over and just below the left elbow were two groups of multiple nodules; each group was about 1¼ in. in diameter. There was a large firm nodule on the left heel and a firm nodule on the bottom of the left foot. There was a smaller nodule on the right elbow and a similar one on the left wrist. The sedimentation rate was 50 mm. per hour, corrected. Roentgenograms showed decalcification of the bones and swelling of soft tissues around the affected joints. All other laboratory findings were within normal limits.

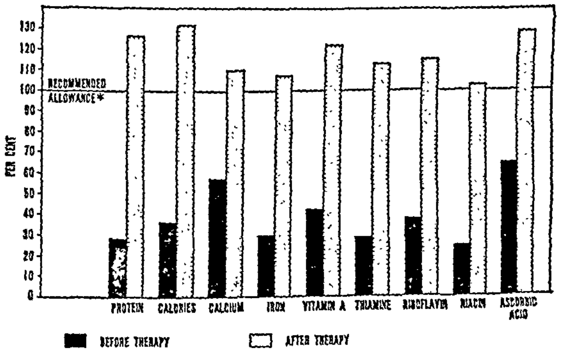

Fig. 9.—Nutrients supplied by diet of patient with rheumatoid arthritis before and after cortisone therapy.

He was given a total of 1,900 mg. of cortisone acetate (Merck) intramuscularly in a period of six days. The pain in the involved joints began to subside three hours after the first injection; his hands began to "relax," and there no longer was any tension in his shoulders and elbows. He slept more that night than he had in a long time. By the following morning the swelling in his right ankle had subsided and he could close his hands completely for the first time in several years. He stated that he never had had as much relief from any other therapy. Gradually all the swelling and soreness of the joints disappeared, so that he could walk and move around with ease, and the nodules became softer. His sedimentation rate decreased to 30 mm. per hour with correction.

For the past four years he has been given therapy intermittently either with cortisone acetate (Merck) intramuscularly or orally or with corticotropin (Armour) intramuscularly. In from four to five days to a month some pain and discomfort return, but they never have been so severe as before the first period of therapy, and he is able to work regularly driving a coal-loading truck. He eats a great deal after therapy with either corticotropin or cortisone acetate, as shown in figure 9. Without treatment his sedimentation varies between 40 and 50 mm. per hour, corrected, and after therapy it decreases to about 17 mm. per hour, corrected. This patient, like many others in the clinic, cannot work without treatment. When enough therapy is given, the symptoms disappear; his strength and appetite return, with the result that he is able to do heavy manual work and support himself and his family.

When one looks at the major causes of death in 1900 and contrasts them with the major causes of death in 1950 in the light of the studies that I have just reported, it is obvious that heart disease, carcinomas, and vascular lesions of the nervous and renal tissues should be approached from the nutritional and metabolic point of view. We propose to do this at our institute in Chicago.

SUMMARY AND CONCLUSIONS

In our studies in the past 25 years, which are touched on briefly here, we have stressed that the lack of proper growth and development of infants and children is a chemical and clinical problem and that the process of aging and illness should be approached as a chemical as well as a clinical problem. Deficiency diseases in human beings tend to develop slowly, and what many physicians fail to realize is that they are corrected slowly. All too frequently the patient and the physician become impatient because they do not realize the time necessary to restore physiological function that was damaged by a slow and long-drawn-out process. Frequently there is a point beyond which there is some irreversible change.

More should be known of the chemistry of disease. When it is, physicians will not be content to accept the traditional view that when a person is not well, or as one ages, he must expect to lose strength, keenness of vision, and alertness and to look and act "old." The physician can never get away from the challenge to think. There will be no automatic or mechanical diagnosis in the near future. The physician who has an uncanny sensitiveness associated with a capacity for memory and experience is needed more in this field than in any other. He must have in mind that there is nothing constant in the human body. The nutrients ebb and flow into the cells. They all bear potentials for change. In this ever-shifting, ever-renewing of the constituents of the body, the cells must be renewed or there will be deterioration. These forces shape the patient's destiny.

As an outgrowth of 25 years' work, the following four essentials for therapy in nutritive failure have been devised: (1) diet—adequate calories, adequate protein, vitamins, and minerals in suitable and edible form for the individual person; (2) basic supplement—vitamin A, thiamine, riboflavin, nicotinamide, ascorbic acid, folic acid, vitamin B_{12}, and "activator" when necessary [8]; (3) additional medication—as indicated for coexisting diseases; (4) natural B complex—dried brewers' yeast powder or liver extract.

The basic formula for the treatment of clinical syndromes of mixed vitamin deficiencies is as follows:

	Daily	
Folic acid	5 mg.	
Thiamine	10 mg.	
Nicotinamide	150 mg.	
Riboflavin	10 mg.	
Ascorbic acid	150 mg.	
Vitamin B_{12}	10 to 15 mcg.	(Usually very large amounts are needed unless highly potent activator is used)

Pregnancy, lactation, growth, and aging result in special stresses on nutritional processes of the body. It is well known that improper diet is not the sole cause of dietary deficiency diseases but that impaired absorption from the alimentary tract, failure of utilization by the tissues, and inadequate storage may be contributing factors. I have tried to stress that the problems presented by patients with deficiency diseases vary greatly and that it is necessary for the physician to give careful consideration to the problem presented by each patient and to prescribe the type of therapy best suited for him. The treatment must restore health as quickly as possible and must prevent recurrence of the disease. The physician should prescribe, in addition to specific therapeutic agents, a diet that the patient can eat and digest satisfactorily. Sole reliance on dietary therapy is inadvisable and impractical. It is better to prescribe too much of the therapeutic agents indicated rather than too little, too soon rather than too late. Precise diagnosis allows one to avoid futile treatment.

Use of nutrients to replenish the tissues and to prevent disease is the physician's primary problem. He knows that the nutrients must be supplied for the body from the outside. No statistics can determine the loss or no words can describe the waste that occurs when physicians do not meet this challenge head on. In unpublished observations by Dr. Robert E. Stone and myself, we have shown that synthetic cortisone acetate (Merck), pituitary corticotropin (ACTH) (Armour), and corticotropin zinc phosphate (Organon) each profoundly affects the nutritional processes. Many severely ill patients have been observed to double their food intake soon after taking any one of these substances.

The little that is known and the much that should be known lead to confusing and contradictory information. It should be recalled that the chemical equilibrium of the human body is preserved in many ways and that the maintenance of this equilibrium becomes more and more difficult as the stores of protective substances are depleted by various disease processes. It is clear that many persons have placed too narrow a significance on the importance of nutrition and metabolism in the general physiological process. Patients must have an adquate intake of the needed nutrients, which must be properly assimilated and utilized, if the physician is to be expected to take the best care of them.

[8] "Activator" is intrinsic factor that must be given in adequate amount to form conjugate of vitamin B_{12} present.

PATHOGENESIS OF CONSTRICTIVE PERICARDIUM

Eli Moschcowitz, M.D., New York

We are well conversant with the clinical and anatomic aspects of the fully developed constrictive pericardium, but, so far as I am aware, no study has been made of the pathogenesis or the clinical phases of the early and intermediate stages. Inasmuch as the course of constrictive pericardium covers many years, the opportunity to observe its development from the beginning to the terminal phase must come but rarely. For the most part, we are forced to reconstruct the pathogenesis by a study of the anatomy and incidence of pericardial adhesions under all conditions. Such a program obviously necessitates an inquiry into the still unsettled cause of constrictive pericardium. With these objects in view, I investigated the autopsy findings and some of the clinical aspects of all the cases of adherent pericardium found at post mortem in the Mount Sinai Hospital during the past 25 years.

DEFINITION

A constrictive pericardium is one in which the two layers of the pericardium are universally adherent and thickened in such a way that they interfere with some of the normal functions of the heart, especially diastolic filling. In addition, torsion of the heart clockwise or counterclockwise on its long axis[1] and compression of the entering veins by the adhesions act to produce cardiac insufficiency and/or lessening of the stroke volume.

Although there is no doubt that adhesions between the parietal and visceral layers of the pericardium represent the earliest anatomic phase of constrictive pericardium, a totally adherent pericardium alone does not imperil cardiac function to any appreciable degree. Postmortem records are replete with instances of uncomplicated, complete synechia of both layers even in elderly patients who have never suffered from cardiac distress. This lesion has been termed accretio cordis and, by some observers, has been sharply differentiated from concretio cordis or constrictive pericardium. Such a distinction, I believe, is not justified, and I shall try to show that sometimes accretio cordis is the earlier stage of constrictive pericardium.

Constrictive pericardium is nearly always associated with adhesions from the external surface of the pericardium to the surrounding structures, either the sternum, the adjacent surfaces of the pleura, the diaphragm, or the mediastinum; also, there are more or less generalized pleural adhesions. Frequently the peritoneum is thickened and adherent, especially on the convex surfaces of the liver and spleen. These manifestations can be attributed to a previous polyserositis the causes of which will be discussed later. To what degree the adhesions from the pericardium to the surrounding structure cause interference with function still remains to be determined. Hosler and Williams [2] performed various experiments on dogs; in some, they sewed the parietal pericardium to the diaphragm, and, in others, they sewed the two layers of the pericardium together and then to the diaphragm. In both instances, circulatory disturbances did not ensue, and tolerance to vigorous exercise on a treadmill was normal. The animals were observed over a period of two and a half years. Postmortem examination revealed no cardiac hypertrophy.

Clinically, constrictive pericardium, in its advanced stages, is associated with a rather classic syndrome. The syndrome has been admirably summarized by Burwell and Blalock.[3] 1. The venous pressure is high and persistent. 2. The systolic pressure is low; the pulse pressure is low; and there is pulsus paradoxus. 3. The heart rate is rapid and becomes excessive on exercise. 4. Both fluoroscopy and kymography show a diminution of excursion of the ventricle that is more marked in the right side. 5. The total blood volume is increased. 6. The velocity of blood flow (arm to tongue and arm to carotid) is prolonged. 7. The output of the heart per minute is diminished. To these we may add anasarca, especially ascites. This syndrome is not pathognomonic for constrictive pericardium; it also occurs in cases of tricuspid stenosis and prolonged cardiac tamponade. But it must be emphasized that it only occurs in cases of full-blown constrictive pericardium and, therefore, cannot serve as a diagnostic approach to the early stages. Aside from the pericardial lesion itself, investigations on the finer morbid anatomy of the visceral lesions have been desultory. Emphasis has hitherto been almost entirely centered on the clinical and operative aspects of the disease.

The persistent, high venous pressure so characteristic of constrictive pericardium would lead one to infer that phlebosclerosis must result not only in the systemic but also in the portal veins. Such indeed is the case. Phlebosclerosis of the hepatic veins, which I described many years ago in association with hypertension of the pulmonary circulation,[4] was found in every one of our patients with constrictive pericardium. In a study of congestive splenomegaly,[5] I tried to show that the essential lesions, namely, fibrosis of the pulp (Billroth) cords, sinus hyperplasia, and fibroadenia, occurred only in persistent hypertension of the portal circulation, whether the result of cirrhosis of the liver, obstruction of the portal or splenic veins, or any cardiac disorder in which a persistent venous pressure is demonstrable. The fibrosis of the pulp cords was interpreted as a capillary sclerosis. These morbid changes were also present in every case of advanced constrictive pericardium in this series. In a recent study of cardiac fibrosis (cirrhosis) of the liver,[6] I tried to show that the fibrosis is largely the result of the simultaneous association of prolonged hypertension of both the pulmonary circulation and the portal circulation. As a result, phlebosclerosis of the hepatic veins is engendered with capillary sclerosis of its tributaries, in the outflow tract of the organ, and phlebosclerosis and capillary sclerosis of the tributaries of the portal vein, in the inflow tract. This lesion also occurred in all our cases

Because of space limitations the bibliographic references have been omitted from THE JOURNAL and will appear in the author's reprints.

of constrictive pericardium. Finally, I have shown [7] that arteriosclerosis of the pulmonary artery and sclerosis of the alveolar capillaries arise only after there has been a persistent hypertension of the pulmonary circulation, as in mitral disease, emphysema, prolonged congestive failure, pleural adhesions, obliterating lesions of the lungs (tuberculosis and silicosis), and communications between the right and left sides of the heart. In consequence of the prolonged, elevated venous pressure, hypertension of the pulmonary circulation must arise in constrictive pericardium. This has been demonstrated by cardiac catheterization.[8] Every case of constrictive pericardium in this series has shown sclerosis of the pulmonary capillaries manifested by thickening and occasionally by hyaline degeneration, with secondary dilatation.

The association of visceral capillary sclerosis with either phlebosclerosis or arteriosclerosis in organs in which afferent or efferent vessels are subjected to increased arterial pressure (lungs, pancreas, and spleen) or to an increased venous pressure (liver) is a universal principle [9] and is the cause of the increased fibrosis in these organs under such conditions. These changes are viewed as compensatory to the increased pressure. These capillary scleroses of the lung, the liver, and the spleen, with their attendant scleroses of the main afferent and/or efferent vessels, are, other factors being excluded, the distinctive features of constrictive pericardium and serve as anatomic criteria to differentiate accretio cordis from constrictive pericardium. The constriction may be just enough to induce capillary sclerosis, and, if the venous hypertension is not excessive and, especially, if it is not too prolonged, the patient may be entirely asymptomatic. The constrictive pericardium thus becomes an anatomic but not necessarily a clinical entity.

This differentiation in terms of morbid anatomy is emphasized because constrictive pericardium is currently viewed as a combination of both anatomic and clinical characters, and its diagnosis is not considered valid unless both are present.

ETIOLOGY

Inasmuch as the cause of constrictive pericardium is closely allied to that of adherent pericardium, I investigated the cause of all our cases of adherent pericardium. Only the cases which the adhesion was dense and scarlike were included; those in which it was fresh or intermediate were omitted. In 9,618 autopsies, such adherent pericardiums occurred 130 times, or in 1.4%.

On review of these 130 cases, it was found that the causes of adherent pericardium, complete or partial, were rheumatic fever, 46.2%; coronary thrombosis, 18.5%; tuberculosis, 3.1%; no apparent cause (as determined by history and autopsy), 25.5%; polyserositis with indeterminate endocarditis, 4.5%; polyserositis without endocarditis (associated with a typical scleroderma), 0.7%; and syphilis, 1.5%. Of the syphilitic patients, the Wassermann reaction of one was 4+, and the other had a typical hepar lobatum. The pericardial lesions were not structurally syphilitic. In the same 130 cases, the pericardium was completely adherent in 71 (54.6%). The causes, in this group included rheumatic fever, (38), 53.5%; coronary thrombosis (6), 8.5%; tuberculosis (3), 4.2%; no apparent cause (19), 26.8%; polyserositis with indeterminate endocarditis (4), 5.6%; and miscellaneous (1), 1.4%. If rheumatic fever is considered to be a cause of a polyserositis, the latter caused complete obliteration of the pericardial sac in 64.4% of all cases.

The term polyserositis requires a stricter definition, because it has been applied indiscriminately to include both exudates and transudates. I have limited the term to include only those that are strictly inflammatory. Of the six cases, five were classified as indeterminate or atypical endocarditis as described by Libman and Sacks.[10] In one, polyserositis was associated with a scleroderma but not with endocarditis. It is worthy of note that the pericardium, pleurae, and peritoneum were involved in six. If we include the cases of tuberculous pericarditis and rheumatic fever, which strictly speaking may be classified as polyserositis since all three serous cavities were affected, we note that polyserositis, exclusive of instances in which its origin is unknown, accounts for a completely adherent pericardium in 64.4%. I think that polyserositis of unknown origin associated with the type of endocarditis described by Libman and Sacks is important because it may be one of the causes of a constrictive pericardium, an observation that has not been made before. In one of my cases, clinical and anatomic constrictive pericardium was previously classified as of unknown origin. Postmortem observations on cases of endocarditis described by Libman and Sacks, whether associated with lupus erythematosus or not, reveal an unusually intense polyserositis characterized by an unusual quantity of gelatinous mucoid exudate in the pericardium and pleurae and on the surface of the liver and spleen. It is very possible that healing of such a polyserositis may result in development of the anatomic characteristics of constrictive pericardium. Obviously, only a postmortem examination can disclose this variety of polyserositis, and, therefore, no etiological classification of constrictive pericardium can be completely valid without a study of the morbid anatomy of the cardiac valves.

Of the 130 cases of adherent pericardium, a constrictive pericardium in an anatomic but not necessarily in a clinical sense occurred in 7, or 5.4%. Only four conformed to the classic clinical and anatomic criteria of the disease; that is, they represented the most advanced stages of constrictive pericardium. The remaining three cases may be viewed as examples of the early phases; first, because anatomically they possessed many characteristics of constrictive pericardium and, second, because they showed the characteristic capillary sclerosis in the lungs, liver, and spleen described previously.

REPORT OF CASES

CASE 1.—A 49-year-old woman gave a history of ascites, dyspnea, and anasarca that had been present for three years. She had had many paracenteses. Physical examination showed marked ascites and venous pressure of 16.5 cm. H_2O that rose to 22 mm. on right upper quadrant pressure. The circulation time was 18 seconds and the ether time 8 seconds. Pericardiectomy was performed, with perforation of the right ventricle. Hemorrhage occurred, and death followed.

Autopsy showed polyserositis; total adhesive pericarditis, with calcification; both pleurae adherent and thickened; chronic perihepatitis; chronic perisplenitis; thickening of parietal peritoneum; ascites; phlebosclerosis of the vena cava and hepatic veins; cardiac fibrosis of the liver; chronic passive congestion of the spleen, with splenomegaly; bronchopneumonia; and varicose veins of the mesentery of the small intestine. The heart weighed 425 gm.; the right auricle was slightly dilated; and the left ventricle was contracted. The pericardium was thick and calcified throughout. The spleen weighed 40 gm. The liver weighed 1,490 gm. and was fibrotic.

Microscopic examination revealed that the alveolar capillaries of the lungs were thickened and dilated (capillary sclerosis); many heart failure cells. The pericardium was very thick, hyalinized, and calcified. The liver showed advanced cardiac fibrosis, and the intima of the hepatic vein and vena cava was greatly thickened. The spleen showed a typical early phase of congestive splenomegaly, namely, sinus hyperplasia, fibrosis of pulp cords, fibroadenia; and a thickened and hyalinized capsule.

This patient presented the typical clinical and anatomic manifestations of a constrictive pericardium. The history and autopsy, however, revealed no obvious cause.

CASE 2.—At the age of 24, this man had severe upper quadrant pain with fever. On exploratory laparotomy, the gallbladder was found to be normal. Eight months later, he was reexplored because of severe pain in the right lower quadrant. Only a much thickened capsule of the liver (Zuckerguss) and some abdominal fluid were found. At the age of 39, the man was hospitalized because of ascites and bilateral pleural effusions. The venous pressure was 25 cm. H_2O. Pericardiectomy was performed, but the patient died two days later.

The findings at autopsy included constrictive pericardium; perforation of the right ventricle; pleural adhesions and thickening; arteriosclerosis of pulmonary artery; cardiac fibrosis and chronic congestion of the liver; marked hypertrophy and dilatation of both auricles; hypertrophy of both ventricles; intimal thickening of hepatic veins and superior and inferior vena cava; anasarca; hydrothorax; indeterminate endocarditis of aortic valve; and bilateral healed apical tuberculosis. The pericardium was dense, firm, and 1 cm. thick. The right auricle was greatly dilated and hypertrophied; the tricuspid valve was dilated. On the edge and anterior surface of the right posterior aortic cusp there was a gray-pink, wart-like nodule that measured 3 by 2 mm.

Microscopic examination of the lungs showed capillary sclerosis with many heart failure cells. The pericardium was greatly thickened and hyalinized. The wart-like nodule at the aortic valve was densely fibrous. The liver showed centrolobular necrosis, and the intima of the hepatic veins and inferior vena cava was markedly thickened. The spleen showed sinus hyperplasia, fibrosis of the pulp cords, and lymphadenia. The capsule was thickened. This patient presented a typical clinical syndrome of constrictive pericardium confirmed both by operation and autopsy, with typical pulmonary capillary sclerosis, cardiac fibrosis of the liver, phlebosclerosis of hepatic veins and inferior vena cava, and congestive splenomegaly. The indeterminate endocarditis described by Libman and Sacks leads to the suspicion that there had been an asymptomatic nonspecific polyserositis in the past, an association that is quite common.

CASE 3.—This 25-year-old woman had had "heart trouble" since youth, with numerous episodes of congestive failure. A roentgenogram of the heart showed extensive calcification of the pericardium. Pericardiectomy was performed twice, four and two years earlier, with some relief after each operation. Eventually the patient died in congestive failure.

Autopsy, after resection of the sternum and pericardiectomy, revealed rheumatic heart disease; chronic adhesive calcified pericardium; chronic valvulitis of the mitral valve, with stenosis and insufficiency; chronic valvulitis of the aortic and tricuspid valves; dilatation and hypertrophy of both auricles and ventricles; bilateral pleural adhesions; chronic, passive congestion of the viscera; bilateral pleural effusion; ascites; chronic perihepatitis and perisplenitis; arteriosclerosis of the pulmonary artery; and cardiac fibrosis of the liver. The heart was much enlarged. The pericardium averaged 1 cm. in thickness and was calcified throughout. The pericardium was adherent to the anterior chest wall, adjacent pleurae, and mediastinum. The valves showed lesions typical of rheumatic fever, but no Aschoff's nodes were found. The alveolar walls of the lungs showed capillary sclerosis; the alveoli contained heart failure cells. The liver showed severe cardiac fibrosis. The spleen showed fibrosis of the pulp cords and some sinus hyperplasia. There was marked perisplenitis and perihepatitis.

This woman presented the clinical manifestations of constrictive pericardium and multiple valvulitis of rheumatic origin. Microscopic examination showed capillary sclerosis of the lungs, the liver (cardiac fibrosis), and the spleen (congestive splenomegaly). To what extent these lesions were the result of the constructive pericardium or of the associated valvular disease, it is impossible to say. In all probability, one was superimposed on the other as suggested by the severity of the microscopic lesions.

CASE 4.—The patient was a physician in whom pulmonary tuberculosis and a pericardial effusion developed eight months before his hospitalization. The liver and spleen were enlarged. The venous pressure was 23 cm. H_2O. Pericardiotomy and pericardiectomy were performed during which an enormously thick pericardium was removed. Biopsy from the anterior surface of the pericardium demonstrated tuberculosis. After the operation, the venous pressure dropped to 5.5 cm. H_2O; later, an empyema was drained. Continuous fever and cachexia developed, and the patient died.

Autopsy, seven and one-half months after partial pericardiectomy and pericardiotomy, revealed chronic tuberculous pericarditis; miliary tuberculosis of the lungs, kidneys, and spleen; extensive bilateral pleural adhesions; hypertrophy of the left side of the heart and arteriosclerosis of the aorta and systemic arteries (the protocol did not mention whether the pulmonary artery was arteriosclerotic); granular perihepatitis; hydronephrosis and caseous tuberculosis of left kidney; tuberculosis of mediastinal lymph nodes; and splenomegaly. The heart was enlarged, and there was marked hypertrophy of the right side of the heart and of the left ventricle. The pericardial sac was distended. The wall was between 5 and 7 mm. thick. The external surface was adherent to the adjacent pleura. The capillaries of the pulmonary alveolar walls were dilated and thickened, and the alveoli contained heart failure cells. The surface of the liver was covered with fibrous deposits and showed central congestion. The portal spaces were filled with inflammatory cells. The spleen showed some sinus hyperplasia and slight fibrosis of the pulp cords. All the organs showed many tubercles.

As in case 3, the clinical phenomena were so dominated by tuberculosis that any symptoms referable to constrictive pericardium were largely suppressed; nevertheless, capillary sclerosis in the lung and in the spleen indicated that constriction of the pericardium was active.

CASE 5.—As a child, this 14-year-old boy had measles and frequent colds. He had always been underdeveloped and had had diarrhea since the age of seven. The stools were foamy and bulky, and the boy had secondary anemia. He was admitted to the hospital one year before the present admission. At that time, his condition improved on a diet high in carbohydrate and low in fat content supplemented with iron and liver extract. His liver then was large, and his spleen was palpable two fingerbreadths below the free border of the ribs. His present admission followed an appendectomy performed five days previously. He died with symptoms of intestinal obstruction.

Autopsy showed acute ileus caused by an omental band; chronic ulcerative colitis; parietal thrombi in the superior mesenteric and portal veins; chronic interstitial hepatitis; splenomegaly (the spleen weighed 420 gm.); and chronic adhesive pericarditis, with phlebosclerosis of the inferior vena cava and hepatic veins. The heart was normal in size, and the valves were intact. The pericardium was 0.5 cm. thick, and the pericardial cavity was completely obliterated. The lungs showed dilatation and thickening of the alveolar capillaries and a few heart failure cells in the alveoli. The liver showed phlebosclerosis of the hepatic veins and inferior vena cava and slight interstitial hepatitis. The spleen showed fibrosis of the pulp cords, sinus hyperplasia, and marked congestion. There were numerous fibrous thrombi in the submucosal vessels of the large intestine with beginning organization and large parietal thrombi in the superior mesenteric and portal veins.

The pericardial lesion was surely independent of the ulcerative colitis. While symptomless, the thickened and totally adherent pericardium must have caused hypertension of the pulmonary circulation as manifested by the pulmonary capillary sclerosis and the heart failure cells. Also there must have been persistent peripheral venous pressure as evidenced by phlebosclerosis of the hepatic veins and of the inferior vena cava and hypertension of the portal circulation as manifested by an early, congestive splenomegaly. The slight interstitial hepatitis was probably of nutritional origin. Had the boy lived, the probability is strong that the clinical evidences of an advanced constrictive pericardium would eventually have developed. No cause for the totally adherent pericardium was discovered.

CASE 6.—A 51-year-old man had pain in the chest with dyspnea, orthopnea, and cyanosis, four weeks before admission. The blood pressure was 124/70 mm. Hg. The liver extended five fingerbreadths below the free border of the ribs. The venous pressure was 18 cm. H_2O. The electrocardiogram resembled that of a coronary closure. The patient was treated with mercurial diuretics but gave no response.

At autopsy the pericardium was completely obliterated and partially calcified. There was primary carcinoma of the liver; carcinomatous invasion of the right hepatic and the portal vein; massive occlusion of the right pulmonary artery; multiple emboli in the lungs; dilatation of the right auricle and ventricle; cardiac fibrosis of the liver; multiple pleural adhesions; and metastatic nodules in both lungs. The pericardium was greatly thickened and hyalinized and contained a calcific girdle 0.5 cm. thick that enveloped the middle and much of the ventricular portion of the heart. Except for a note of the presence of emboli, the pulmonary arteries were not described in the protocol.

On microscopic examination, the pulmonary capillaries were dilated and tortuous; the liver showed cardiac fibrosis and phlebosclerosis of the hepatic veins; and the spleen showed congestion but no congestive splenomegaly.

This case may be interpreted as one of anatomic constrictive pericardium of unknown origin, and, although symptomless, it was sufficient to cause hypertension of the pulmonary circulation as manifested by capillary sclerosis of the lungs and persistent systemic venous hypertension as evidenced by cardiac fibrosis of the liver and phlebosclerosis of the hepatic veins. Had death caused by carcinoma not intervened, I believe that the clinical manifestations of a constrictive pericardium would have developed. No cause for the pericardial lesion was discovered.

CASE 7.—A 17-year-old boy had had weakness for three months, cough for three weeks, and fever and signs of fluid in both sides of the chest and abdomen. The spleen was palpable. Twelve weeks before his admission, his family physician discovered signs suggestive of pericarditis. He had dyspnea on exertion, orthopnea, and edema of the lower extremities. Congestive failure developed, and the patient died.

Autopsy revealed bilateral pleural effusion; ascites; complete obliteration of pericardial sac; tuberculous pericarditis; disseminated tuberculosis of the lungs, spleen, kidneys, and lymph nodes; chronic, passive congestion of the liver and phlebosclerosis of the superior and inferior vena cava and of the hepatic veins; arteriosclerosis of the pulmonary artery; mediastinal adhesions; and peritoneal tuberculosis. The pericardium averaged 1.5 cm. in thickness. It was hyalinized, and, on its inner aspect, there were many caseating tubercles.

Microscopically, aside from tuberculosis, the lungs showed sclerosis of the alveolar capillaries; the liver showed central congestion; and there was phlebosclerosis of the hepatic veins and of the superior and inferior vena cava. The spleen showed sinus hyperplasia and fibrosis of the pulp cords; in other words, congestive splenomegaly.

I believe this case demonstrates anatomically an early, constrictive pericardium. The presence of pulmonary arteriosclerosis and alveolar capillary sclerosis shows that there was prolonged hypertension of the pulmonary circuit. Phlebosclerosis of the hepatic veins and of the inferior vena cava and the early phase of congestive splenomegaly all indicated that there was sustained peripheral and portal venous pressure. The clinical phenomena were so masked by tuberculosis that it is impossible to say to what extent the constrictive pericardium was responsible for the symptoms.

COMMENT

An analysis of these seven cases provokes a number of interesting deductions. First, it is obvious that constrictive pericardium, in the anatomic sense, does not always give rise to the classic clinical phenomena. Inasmuch as the clinical evidences are mostly the results of the morbid visceral anatomy as revealed in the vascular and capillary scleroses, especially of the lung, the liver, and the spleen, induced by prolonged venous hypertension both systemic and portal, one may conclude that the intensity of the clinical phenomena is largely dependent on the duration of venous hypertension. The degree of venous hypertension is probably of less importance. I have shown in studies on congestive splenomegaly [5] and cardiac fibrosis of the liver [6] that these lesions are dependent more on the duration than on the severity of venous hypertension. Second, in regard to etiology, my observations are not entirely in accord with those of other observers. In three cases, no cause was obtained from the history or at autopsy. One was associated with rheumatic fever, and, while there is no absolute proof that the constrictive pericardium was a result of this disorder, the probability is strong that it was the result of a rheumatic polyserositis. Two cases were undoubtedly caused by tuberculosis, and, in one, the presence of an indeterminate endocarditis of the type described by Libman and Sacks suggests that a nonspecific polyserositis preceded the constrictive pericardium.

Paul, Castleman, and White [11] described 53 cases. In 56.5%, no cause was discovered. Tuberculosis was demonstrated in 17%. There was no sharp distinction between the microscopic picture of healed tuberculous pericarditis and so-called idiopathic constrictive pericardium. In two cases, healing tubercles were found during surgery, but no evidence of tuberculosis was found at post mortem two and three years later. In none of the 53 cases was there a history of rheumatic fever. In three cases there was a history suggestive of pericarditis some years previously.

Martensen and Warburg [12] report rheumatic fever in 2 out of 25 cases. Tuberculosis was verified by histological examination in three cases; in two other cases, it was probable. In two, constrictive pericardium was due to trauma; in one, to blunt violence and, in the second, to a gunshot wound. In the remaining cases, the cause was obscure. In this connection, Strauss [13] reports a case in which constrictive pericardium was due to a needle left in the pericardium for seven years after diagnostic aspiration. Joest [14] states that foreign bodies have been ingested by cows and, after ulcerating through the diaphragm, have come to rest in the pericardial sac and produce a septic inflammation with total synechiae, hyalinization, and calcification resulting in a constrictive pericardium. Blalock and Burwell [15] found the tubercle bacillus in 21 of 28 cases in which the cause could be established by operation, aspiration, or autopsy. Staphylococci were found in 3 of the 28. In an earlier publication,[3] these same authors found not a single instance caused by rheumatic fever. McKissick [16] reports 20 cases of which he regarded 8 to be caused by tuberculosis as evidenced by a history of prolonged exposure to tuberculosis, by biopsy of the pericardial scar, or by the presence of tuberculosis in other sites, such as the bones, lymph nodes, or lungs. In the other 12, the cause was unknown. McKissick also reports verification by biopsy of a tuberculous pericardial effusion that, after 20 years, developed into a constrictive pericardium. Of 24 cases, Harrington [17] found tuberculosis confirmed by biopsy in 5. In the remaining 19, the cause was unknown. Sellars [18] found tuberculosis in 16 out of 20 cases of constrictive pericardium. In a later publication,[19] he described 18 cases of tuberculous pericarditis. In 4 of these, no other serous cavity was affected, and, in 16, constrictive pericardium developed.

Apparently there is a wide discrepancy in these reports with respect to the incidence of the various causes. There is no doubt that tuberculosis is a fairly common cause and that probably over half the cases reveal no ascribable cause. There is a very wide divergence with respect to the incidence of rheumatic fever as a cause. In one of our seven cases, rheumatic valvulitis was found at autopsy. The reason our findings differ from those of other workers with respect to etiology is perhaps that we have investigated only postmortem material. Our study does not answer the question of why certain cases of polyserositis result in constrictive pericardium and why others do not. The probability is strong that the result depends on a number of factors; the intensity of primary polyserositis, its duration, and the reactive potentialities of the organism.

SUMMARY AND CONCLUSIONS

The pathogenesis of seven cases of constrictive pericardium, which came to postmortem examination, is described. In four of these (cases 1 through 4), the classic clinical signs and symptoms of constrictive pericardium were apparent. Most of the clinical phenomena may be attributed to sustained hypertension of both the pulmonary circulation and the peripheral venous system, including the portal circulation. As a result of sustained hypertension, there is arteriosclerosis of the pulmonary artery, sclerosis of the vena cava and hepatic veins, and sclerosis of the tributary capillaries of the lungs, liver, and spleen, with the development of sclerosis of the pulmonary capillaries, cardiac fibrosis of the liver, and an early phase of congestive splenomegaly. Three patients (cases 5 through 7) lacked many of the signs and symptoms of contrictive pericardium but had many of the anatomic characters, namely, an unusually thick, totally adherent pericardium. In one case, the pericardium showed considerable calcification and, in a second, complete hyalinization. In addition, there were extensive adhesions to the surrounding pleurae, arteriosclerosis of the pulmonary artery, perihepatitis and perisplenitis, and phlebosclerosis of the hepatic veins and vena cava. There was sclerosis of the pulmonary capillaries in two cases, cardiac fibrosis in one, and an early phase of congestive splenomegaly in two. Three cases may be viewed as disclosing potential constrictive pericardium; in other words, as an earlier phase. Etiologically constrictive pericardium is one of the late results of polyserositis whether from tuberculosis or rheumatic fever or associated with an indeterminate endocarditis, possibly of the type described by Libman and Sacks. Only a postmortem examination is decisive in determining the precise cause.

PRIVATE PRACTICE IN SMALL INDUSTRY

Forrest E. Rieke, M.D., Portland, Ore.

For too many years an ignored paradox in American industry has encouraged an unfortunate parallel in American medicine. In this age of huge corporate manufacturing organizations, only recently has the vast size and great importance of so-called small industries been recognized. In government and business much has been said about the necessity for aiding and preserving the "little fellow," but, because of scattered location and a genius for individual differences, the "little fellow" has not submitted well to organization for aid.

In the field of industrial medicine it has been possible to develop highly coordinated and skilfully staffed medical, surgical, and health conservation programs for big industrial groupings. Similar services have not been readily assembled for small industry.[1] Brief reference to figures shows both the urgency and size of the "small plant problem." National statistics have been drawn together by Klem and McKiever [2]; from this source the table in the next column is taken. The table shows that 99% of employee organizations have less than 500 persons, and 70% of total employees are found in so-called small plants. With minor variations these percentages may be applied to most states and large and small cities. In Portland, Ore., in 1947,[3] with a population of 350,000, 80% of the workers were employed in units of less than 500 persons and 55% in units smaller than 100; these figures are substantially the same today.

Size of Class (No. of Employees)	Reporting Units		Workers	
	No. (in Thousands)	Percentage	No. (in Thousands)	Percentage
All units	2,734.2	100.00	35,805	100.00
1 to 49	2,637.9	96.48	14,219	39.71
50 to 499	88.9	3.25	11,085	30.96
500 to 999	4.4	0.16	3,012	8.41
1,000 and over	3.0	0.11	7,489	20.91

WHAT IS THE SMALL INDUSTRY MEDICAL PROBLEM?

Accident rates are more than twice as high in small plants, and sickness disability rates are relatively unimproved in such units. Medical consultation is not accessible and infrequently used by the small plant in the fields of placement examination, job transfer, rehabilitation, psychological evaluation, case finding, and utilization of the aging worker. These and other random

statements are frequently applied, and all are readily substantiated.

Definition of the problem is complicated by absence of a suitable description of the small plant. For my purpose it can be described as the employee group, too small to have afforded or provided physician or nurse service, predominantly composed of less than 250 persons. It is more apt to be a group numbering 20 to 100 employees.

In many places and publications one can find excellent descriptions of industrial medical and health services. When one attempts to apply these services, prohibitive difficulties have been encountered. Most troublesome features of the small plant health problem are to be found in these areas: (1) unawareness that private physicians, primarily in general practice, are in fact the only existing industrial service for most small plants, (2) unfamiliarity of private medical practitioners with industrial health needs and methods, (3) disinterest in improvement of preventive and therapeutic services for industry by these same private practitioners, (4) unfamiliarity of small plant owners with such services and ineptitude at searching for same, (5) unwillingness of owners and many insurance carriers to spend to prevent and conserve in lieu of expenditure to correct illness and injury, (6) failure of community medical agencies and services to foster and coordinate physician-employer ventures in this realm, and (7) a lingering attitude among physicians that service in industry is not as noble, worthy, or ethical as other forms of medical services.

There is much hopeful development as well as discouraging apathy in all of these zones. In an attempt to illuminate problems, methods, and goals and encourage others in private practice to extend efforts to small plants, the following plan is recorded from work in small industries at Portland, Ore. An attempt will be made to relate our experience to the difficulties mentioned.

GENERAL PLAN

In previous articles [4] wartime and postwar transition in Portland's industries was described with its shift of manpower from six huge shipyards to thousands of smaller employee groupings. After the war, in an effort to continue "large industry" medical services akin to those in the war industries, two industrial zone dispensaries were opened in the center of shop areas. These have been operated as a private venture, staffed with physicians and graduate nurses, and maintained solely to provide the services needed by small plants in the surrounding territory. They have not ventured into other medical fields.

Major emphasis has centered on: (1) emergency treatment of industrial injury, (2) diagnosis of minor and incipient ailments and wide referral to private physicians of those with nonoccupational illness, (3) placement and other special examinations relating to job problems and toxicology, (4) collection of industrial medical and toxicological data as reference material for plants, physicians, and nurses, (5) rehabilitation for injured and ill, (6) case finding through examination and survey, (7) plant sanitation, industrial hygiene control, and accident prevention, and (8) consultation with any group seeking help in the improvement of employee health and safety.

In diagnosis and treatment of more extensive industrial injury and occupational illness, full use has been made of a local general hospital and consulting services of all available medical specialties. A high degree of cooperation has been forthcoming from public and private health agencies, most insurance carriers, and most employers. Employee response has varied from apathetic to enthusiastic; repeating business has been gratifyingly frequent.

With the exception of those sent by the employer for placement examination, the employee has not been obliged to come to the dispensaries for services. Absence of compulsion or contractual obligation in either direction has been most worthwhile, obviating abuses ofttimes arising in contract practice. Fees for service are levied against insurance carriers, employers, or the patient, depending on nature of the ailment. Lack of a prearranged retainer has, of course, been a barrier to full use of consultation by small operators.

PROBLEM AREAS

Unfamiliarity of Profession.—As inferred, the majority, if not all, of the industrial medical service reaching employees in small plants comes from physicians devoting most of their time to general practice or the specialties, and certainly not to the specialty of industrial medicine. In the smaller communities physicians often know the details of local industry. In medium-sized and larger cities this is not usually the case. Employers and workers repeatedly complain that physicians in these localities show little awareness of job requirements, injuring forces, chemistry of the job, the impact of illness on the worker, and the dislocation of production caused by his absence. In the dispensaries in Portland there has been some difficulty utilizing physicians as currently prepared for any but the most limited work in relating medical and health factors to demands of the job. Preparation in surgical trauma is good, but work in rehabilitation and conditioning of patients for return to work are unfamiliar to many. It seems that medical schools have not yet managed to acquaint those entering practice with the needs and methods of industrial medicine, a rather glaring deficiency that most schools are doing little to overcome. There is also an evident need for extensive effort to acquaint those already in practice with the same subjects.

Disinterest of Practitioners.—Lack of interest of practitioners in an improved industrial service stems from both physical separation in point of geography and in a fundamental preoccupation with the individual person removed from his environment. Rarely do medical buildings adjoin the industrial work place, and rarer still do physicians visit the work place. Most physicians are greatly stimulated by such visits, and service to the employee-patient is materially improved when his physician knows the daily environment as well as specific chemicals, processes, and hazards in this environment. The employer and employee are pleased when a physician pays a "house call" to his patient's work place. Furthermore, the employer is a willing ally in the ferreting out of noxious occupational agents and assisting in recuperation and rehabilitation when the informed physician phones or writes, seeking help for his patient. Even the unglamorous physical examination gains interest when the physician knows that the worker may be exposed to certain extremely toxic chemicals, or required to make hundreds of exact spatial movements per hour or to drive a 30 ton truck on narrow roads in reduced illumination for six or more hours nightly. The influence of aggravating noise, constant danger, dulling monotony of work, or galling supervision on the psychosomatic disease can be weighed only by the physician interested enough to know of their existence in the patient's daily life.

[4] Rieke, F. E.: Health Service for Very Small Plants Offered Through Private Practice, Occup. Health **12**: 127-129 (Aug.) 1952. Rieke.[1]

Unfamiliarity of Small Plant Owners.—With rare exceptions small plant operators have had no experience with industrial service. When the service exists their desire to purchase it must be considered very low. After six years in the field, there are only small beginnings in use of preventive services other than those in the early care of trauma. The beginnings exist, however. Through observation of our work for larger employee groups, through education by employer organizations, by the chamber of commerce, and by the state board of health, the "little fellows" are becoming aware of their needs and are seeking examination and consultative services. The medical society's role in this regard will be mentioned later.

Failure to Pay for Values Received.—The small plant operator rarely has a budget, to say nothing of planned financial provision, for medical services. Most are unfamiliar even with the cost of accidents as represented by premiums to insurance carriers. Most insurance carriers have not successfully educated the smaller plants in the need for expenditure on preventive medical services. Thus far, so-called union health plans have been equally unproductive in this direction in the Portland area. Insistence by many insurance carriers in industry that their insured merit a reduction in fees by treating physicians has gone far to dampen medical enthusiasm for industrial service. Absence in local offices of insurance carriers of medical consultants and the routine processing of bills and case reports by clerical personnel utterly unfamiliar with medical methods and problems further alienate the interested physician. A further insistence by employers on a very low fee for examination of the employee imparts the conviction to both physician and employee that a competent and searching examination is not desired. On the other hand, the recent trend for employers to ask and pay for a very thorough examination, the earnest effort of many insurance carriers to secure fullest treatment and rehabilitation of the injured, and efforts to arrive at mutually agreeable fees by conference with medical societies all warm the atmosphere in which medical service is delivered and provide a healthier culture medium for growth of interest and fuller physician service. In general, physicians believe that industry deserves the best service available, delivered at fees on a par with those charged other responsible persons and groups in the community. When industrial services are justly valued accelerated growth can be expected. Parenthetically, a most useful summary has been prepared recently by Dr. R. B. O'Connor[5] listing types, costs, and results to be expected in small plant health service.

Failure of Community Group Leadership.—Until recently too few medical societies have exerted leadership or encouraged extension of preventive services in industrial areas. At times there has been actual criticism and obstruction of those toiling in this field. Under the spur of the Council on Industrial Health of the American Medical Association this attitude is changing. Local and state societies have established industrial health committees, and community health councils number many representatives from management and labor.

In Portland a joint committee of the state medical society and the chamber of commerce has held one larger dinner meeting for employers and insurance, medical, nursing, and safety workers, and planning is underway for an area-wide annual conference on industrial health and safety. It is hoped that this may emulate the successful Houston, Texas, conference and other similar efforts. The Oregon state medical society has appointed a liaison committee to meet with representatives of the insurance industry, and it is hoped that this may prove to be an avenue for mutual instruction in the duties and functions of physicians and insurance carriers in their relation to all insured. One of the honored 1952 Sommer Memorial Lectureship speakers brought semiyearly to Portland to address the medical profession was Dr. Rutherford Johnstone, who spoke to large audiences on occupational disease in its various relationships. He stirred a genuine interest among specialists and general practitioners alike.

Recent conferences between the American Medical Association Industrial Council and the Academy of General Practice have clearly illuminated the large potentials for service by this group in industry. A plan is under consideration to include considerable industrial information in postgraduate activities of the academy, and this emphasis will certainly expedite wider participation by its membership.

ETHICAL PRACTICE IN INDUSTRY

Ethics of American medicine exist and are formulated to guarantee a continuing high level of honest, selfless, and devoted service to the public. As times change, methods of practice necessarily change. It is well to remember, therefore, that what is new or strange is not necessarily unethical. As medicine has built on its foundations in the basic sciences, it has added to the bacterial concept of disease and aseptic techniques of surgery the sure knowledge that physical and mental health are best sustained by prevention bulwarked by ever more effective therapeutics. For preventive medicine to be effective it must reach well persons as certainly as the ill. To do this the practitioner must often be the aggressor, and aggressiveness in medicine is frequently considered unethical and may be deleterious. It has been felt, however, that the private practitioner who is critical of those who carry the preventive fight against disease and injury into the limelight of industry is guilty of sins of omission in his too great concentration on treatment of disease. It is hoped that he too will go on the offensive in psychosomatics, case finding, health education, and leadership for health.

---

[5] O'Connor, R. B.: Small Plant Health Programs—Types, Costs and Results, Occup. Health 12: 123 (Aug.) 1952.

Contacts with industry are an ethical extension and improvement of office practice. There is just criticism of those who use industry only as a builder and feeder of practice. Uncondoned also is the pirating of selected patients through industrial contacts. Part of industry's resentment toward medicine arises because many physicians have built a practice in industry and then withdrawn further service. It is to be hoped that private practitioners will increase rather than diminish efforts through industry.

Contacts with employee groups are legitimately made in many ways. In Portland the dispensary's services are introduced through explanatory talks at business and service clubs, patients served in the dispensary and hospital, and other physicians, health agencies, and insurance carriers. Requests are welcomed for new or different services whether for flight or truck operators, lead workers, or meat processors. The work place is visited, and, if puzzled about diagnosis or unsatisfied about work situations, the physicians go to the shop on their own initiative. This is well received and is considered good ethics, for in no other way can the patient's problem be solved. Under patterns described, wherein the medical society and industry are joining hands to become acquainted, worry over legitimacy of industrial service and ethical contacts will be greatly ameliorated.

COMMENT

There are those today who have great plans for the private practice of medicine, whether it be to make it "free," to finance it by prepayment only, to furnish it by groups only, or whatever. I am not among these; I subscribe to the theme so well phrased by Alexander Woollcott when he said, "For the architects of any utopia are inconvenienced by discovery (usually at the last minute) that the human race is not, as at present matured, equipped for the exacting role forced upon it by citizenship in Utopia."

I am impressed by the truly remarkable viability and flexibility of American free enterprise as exemplified medically in the private practitioner. His system is indigenous and for the most part well adapted to local needs. Changing needs have been well met before, and it is reasonable to assume that as methods are improved and needs clarified the small plant industrial problem will be well solved by the practicing American physician.

SUMMARY AND CONCLUSIONS

A private practice serving the medical needs of many small plants in an American city of 350,000 is described. It is observed that the small plant problem can be met best by enlargement of the scope of private practice to fill the preventive and treatment needs of employers and employees. This will require an interested curiosity by practitioners and improved cooperation with public and private health agencies. Expansion of educational activities is urgently needed by medical schools and physician associations to familiarize physicians with industry's needs and methods to fill them. Similarly, wide increase of joint medical society–industry efforts will aid small plant ownership to utilize the private practitioner more effectively. A more honest financial return to physicians in the service of industry will go far to win friends and create a climate for growth. Medical society sponsorship of service for industry will remove many doubts about the ethics involved.

SURGICAL SEPARATION IN CRANIOPAGUS

Herbert J. Grossman, M.D., Oscar Sugar, Ph.D., M.D., Paul W. Greeley, M.D.
and
Max S. Sadove, M.D., Chicago

On Sept. 16, 1951, craniopagus twins were born in Rock Island, Ill. The record of the birth and course during the first six weeks has been adequately described by Durr.[1] The present preliminary communication will give a résumé of the sequence of events that led to the eventual surgical separation of the twins and of the postoperative course.

The babies were admitted to the University of Illinois Hospitals on Oct. 2, 1951. They were in a conjoined state of craniopagus parietalis (fig. 1). Their general condition was good, with normal increments of growth and neuromuscular development. Their measurements on the Stuart-Vickers tables ranged from the 25th to the 50th percentile for their age. The babies had obviously independent activities; they slept at different times, could eat at separate times, made separate movements, had independent bowel and bladder functions, and had individual body temperatures. In all, there was clinical evidence of two autonomous nervous systems. There was a mirror-imaged moderate asymmetry of the head (including the face), the right side of R. L. B. and the left side of R. D. B. being more prominent.

Both babies had systolic murmurs, which were loudest to the left of the sternum at the level of the third interspace. It was considerably louder in intensity in R. D. B. There was no evidence of impaired cardiac function. The left side of the chest of R. D. B. was larger—corresponding to the asymmetry of the face. This was mirrored in R. L. B. The heart sizes were normal. The murmurs were believed to represent an intraventricular septal defect.

The problem at hand was whether or not a surgical separation could be attempted. Unfortunately there was little material in the literature that was of any pertinent

[1] Durr, S. P.: Craniopagus Twins, J. A. M. A. 150:93 (Sept. 13) 1952.

value. The few previous attempts at separation of other craniopagus twins had failed.

Before an actual separation could be attempted, the following basic questions had to be answered: 1. Could the babies withstand numerous diagnostic and operative procedures? 2. Were the brains separate? 3. Was there a dural septum? 4. Were the cerebral arteries separate? 5. Were the venous sinuses separate? 6. Could the anticipated defects in the scalp and skull be closed? Except for the obvious malformation of a conjoined state, results of all studies, including roentgen examination of the chests and long bones, blood studies, and urinalyses, were within normal limits. The systolic murmurs of neither child appeared to be of any functional significance; their general physical condition was good.

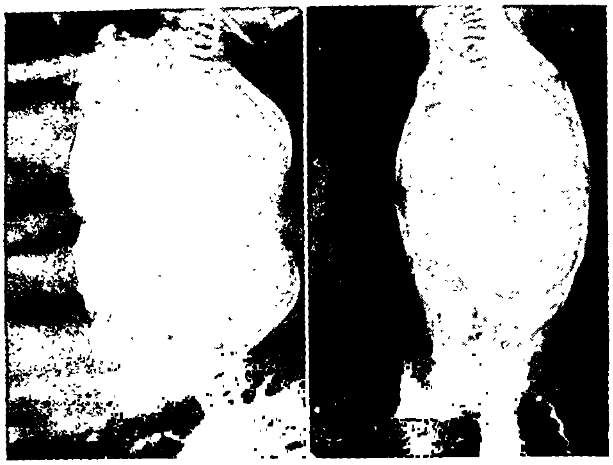

Fig. 1.—Roentgenograms of the skull made at the age of 5 days. Note absence of bony septum and over-riding of parietal bones in the anteroposterior view.

Clinical observation of independent activity indicated the probability that the brains were functioning independently. Electroencephalography disclosed similar but independent patterns of electrical activity normal for their age (2 months). Adequate placement of electrodes over the entire cerebrum was impossible because of the juxtaposition of the heads. Pneumoencephalography (fig. 2) by the lumbar route disclosed separate subarachnoid spaces and indicated a dural septum between the two brains.

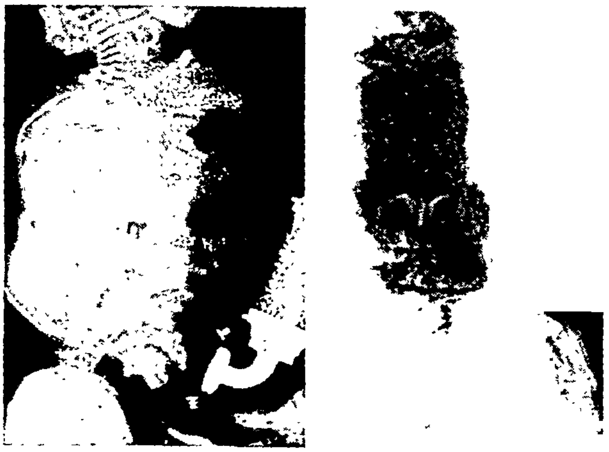

Fig. 2.—Pneumoencephalograms made at the age of 6 weeks. Air was injected into lumbar subarachnoid space of R.D.B. The subarachnoid air is confined to one brain. Note the height of the third ventricle between lateral ventricles. (There was questionable agenesis of the corpus callosum.)

Carotid angiography was carried out after operative exposure of the common carotid artery (the right carotid artery of R. D. B. and the left carotid artery of R. L. B.). Direct intra-arterial injection of iodopyracet (Diodrast) permitted visualization of the intracranial circulation of R. D. B.; owing to technical difficulties, adequate films were not obtained for R. L. B. The films show (fig. 3) independent arterial circulation: the delayed films showed dye in the venous return of only the baby in whom injection had been made. There was no way of accurately predicting from these films what the venous drainage might be. In one attempt at dural sinography through the anterior fontanelle at age 6 weeks, the sinus could not be found. Even through a midline anterior burr hole, the sinus could not be located (age 9 months). At 11 months of age, the junction of the two occiputs was explored, and one parasagittal venous lake was found. Attempts to obtain contrast visualization of this sinus failed.

Fig. 3.—Angiogram in R.D.B. at age 5 months. Iodopyracet (Diodrast) in the middle cerebral artery distribution appears to cross over to the opposite hemisphere, but the midline dye is actually from the anterior cerebral arteries. No dye appears in the cerebrum of R.L.B.

PREPARATION OF SKIN FLAPS

If separation were accomplished, adequate covering for the exposed intracranial structures would have to be provided. It is well known that any free skin graft will grow on exposed brain or dura. It will adhere tightly, however, and such a covering would not be satisfactory, for it would later become necessary to insert some structural support between the skin covering and dura in order to protect the brain. Transplanted skin and subcutaneous fat, but not a free graft, could be reelevated in the future (much as one might do with a normal covering), the mechanical support inserted, and the soft tissue covering then replaced. Since skin with its underlying fat will not grow as free graft, some type of pedicle flap arrangement had to be planned in order to maintain its own viability.

Although specific information concerning the venous drainage systems was inadequate, it was agreed that separation should be attempted. The skin flaps were prepared first. Many different places were considered as the source of the flaps. The most logical solution seemed to be to use direct circumferential flaps taken from around the head. They could be transferred very simply, without discomfort and without the necessity of immobilization in awkward positions. The base of the flaps, in the occipital area, could be brought to the forward part of the skull opening and thus provide some hair where it was most needed. The donor areas from which the flaps were taken could be covered readily with free skin grafts, with which an acceptable cosmetic result might be anticipated.

When the use of scalp flaps had been decided on, it was found by actual measurement that each flap would be approximately 14 in. (35 cm.) long by 3 in. (7.5 cm.) in width. This is very long as compared with the width, especially when the normal blood supply coming in from the vertical axis would be cut off and thus make maintenance of nutrition of these narrow flaps still more hazardous. All of this could be done successfully, however, if sufficient patience and time were used. Repeated "delaying" operations would give adequate circulation if enough time elapsed between the various stages. Each stage would cut off more and more blood supply coming in through the main arteries, namely the frontalis, supraorbital, and superficial temporal arteries of the two sides. As this source of nourishment was gradually diminished, it would simultaneously stimulated increased vascularity rising from the base of each flap in the occipital area and also produce a new additional blood supply in the transverse axis, i. e., parallel to the linear direction of the flap.

The foregoing plan was started on May 14, 1952 (fig. 6, part 1). After three stages, the scalp flaps were completely divided around their peripheries. During the next five months (occupied by several neurosurgical diagnostic procedures) large transverse veins appeared in each flap. These proved to be of inestimable value in preventing venous congestion at the time of transfer. During the first attempt at separation on Nov. 26, 1952, the scalp flaps were elevated completely from their beds. Their blood supply was excellent even though both were 14 in. (35 cm.) long by barely 3 in. (7.5 cm.) wide.

Very early in the course of our observations of the babies, it was evident that there would be numerous diagnostic and surgical procedures, some of which would require an anesthetic agent. During all procedures there was an anesthesiologist with a separate set of instruments (anesthesia machines, laryngoscopes, endotracheal tubes, etc.) with each infant. In each anesthetic procedure, the infants were given only enough of some basal anesthetic agent to produce a state of sleep. This was supplemented by inhalation anesthesia when indicated. Local anesthesia was used as the primary technique where applicable utilizing basal anesthesia by the rectal route with tribromoethanol (Avertin), thiopental (Pentothal), or paraldehyde, and the inhalation of a mixture of nitrous oxide, oxygen, and trichloroethylene as a supplement where necessary. In this way psychic trauma was avoided as the children fell asleep and knew nothing about the procedure. Intubation with soft rubber endotracheal tubes was used in all procedures in which manipulation would endanger the airway.

The respiration of each infant was supplemented or controlled as individually required. At all times, the aim was to have the minimal toxicity at the time of operation and minimal residual toxicity, in order to diminish the possibility of damage from repeated anesthesia. During the operations, continuous consultation between the anesthesiologists and the pediatricians permitted proper fluid replacement. Even in operations done with a small amount of local anesthesia, there was integration of management by all concerned.

In the major procedures that required long periods of time, the problem was magnified by the blood loss and the danger of trauma to the airway from having the tube in place for as long as 12½ hours. The danger of trauma was accentuated by the manipulations necessary during surgery. The problem was one of maintaining the vital functions throughout. The anesthesia was maintained at a light plane to avoid cumulative damage, but yet had to be deep enough to prevent interference from movement of the patients. The chief agent used was nitrous oxide with as high an oxygen concentration possible. Trichloroethylene was added only for a few minutes at a time to reestablish adequate depth of anesthesia.

FIRST ATTEMPT AT SEPARATION

For the first attempt at separation, an incision was made at the junction of the frontal and parietal bones (right side of R. D. B., left side of R. L. B.), and a channel 1.5 cm. wide from the vertex to the occiput was made. An attempt was then made to split the dura mater into its two fused portions. This proved to be impossible beyond a depth of about 1 cm., because the two leaves of dura mater were fused into one sheet; furthermore, as dissection continued in this plane, there was considerable venous bleeding, the source of which could not be determined. Accordingly, incisions were made on either side of the midline septum, exposing the subarachnoid space on either side of the septum. It could be seen that the dural septum did, in fact, separate two brains; however, because of the peculiar position of the two heads and their immobility with respect to each other, it was impossible to look into the depths on either side of the septum. The dural septum was then incised toward the midline between the two brains. This allowed visualization, at a distance of some 6 cm., of two longitudinal sagittal sinuses that did not appear to communicate with one another in the frontoparietal region, which was the limit of the exposure at this time. This exploration and the antecedent elevation of the scalp flaps had taken six and a quarter hours, and it was felt that complete separation could not be accomplished then and that the procedure should be terminated. The incised dura mater was sutured at its periphery, and the wounds closed. The scalp flaps were resutured into their original beds. The postoperative convalescence was uneventful, except for a short left focal seizure in R. D. B., involving the arm, and lasting less than a minute, that was followed by a mild transient hemiparesis for about 18 hours.

FINAL SEPARATION

The final separation was made on Dec. 17, 1952. This was started at the frontal junction with an incision made parallel to the dural septum and a few millimeters from it, to avoid the bleeding encountered when separation of the dura mater had been attempted in the earlier operation. It was believed that the dural defect created by going on R. L. B.'s side of the septum might be covered with polyethylene film. The falx of R. L. B. was found and cut while the numerous vessels were clipped as necessary. After a few centimeters of exposure, it became evident that, in order to permit visualization into the depths, it would be necessary to clip the veins running from the surface of the brain to the dural septum. This would inevitably interfere with the venous return from one of the twins. By the time this information was obtained, there was enough interference with the brain of R. L. B. that it was clear that complete separation would not markedly increase the impairment of cerebral function already anticipated (fig. 4). Accordingly, the falx was cut completely, and the veins that drained the surface of R. L. B.'s cerebrum were also clipped and cut as they entered the dural sinuses. These were found to be three in number (fig. 5); they lay within the dural septum. One was far out in the periphery, forming a semicircle on the left side of R. D. B.'s brain, and there was one on either side of the cut falx, which had extended from R. L. B.'s brain to the dural septum. It was possible to reach the posterior part of the falx where there were huge venous lakes connecting all of the lateral sinuses and all of the sagittal sinuses, as well as the circumferential sinus posteriorly in what amounted to a conjoined torcular Herophili. With the incision being made on R. D. B.'s side, these enormous conjoined sinuses were cut through. Hemostasis was obtained with difficulty, and the babies went into shock, which was counteracted by liberal administration of blood.

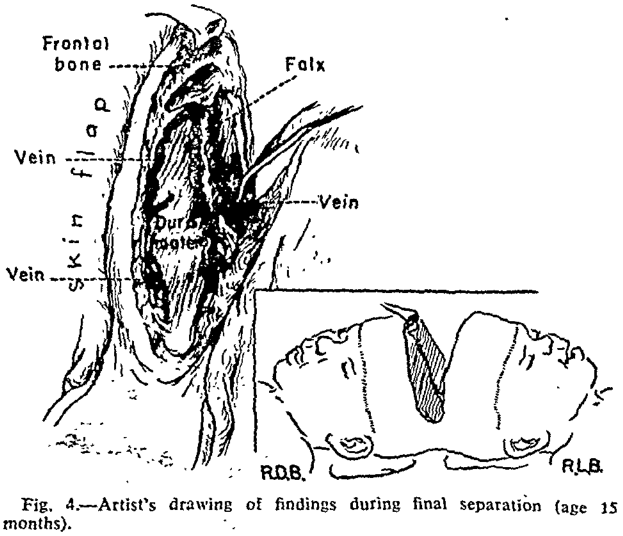

Fig. 4.—Artist's drawing of findings during final separation (age 15 months).

Thus was accomplished the complete separation of the two infants, 10½ hours after the operation was begun. R. L. B.'s brain had the typical appearance of congestion with petechial hemorrhage that would be expected from a brain with an intact arterial supply but virtually no venous outflow. R. D. B.'s brain appeared to be normal except for some congestion and edema in the right parietal region where the dural septum was defective, presumably as a result of failure of healing of the incision made in the dural septum on that side in the first separation attempt.

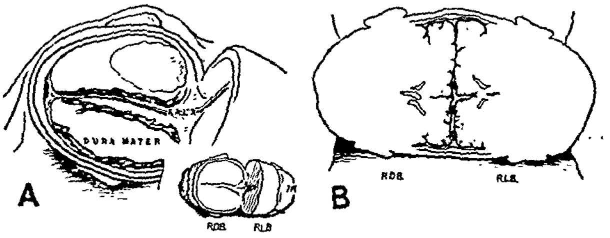

Fig. 5.—*A*, diagram of arrangement of abnormal dural venous sinuses as disclosed by operation. Note the dural defect over the right hemisphere of R.D.B. *B*, reconstruction of arrangement of dural venous sinuses, seen in coronal section. Note the apparent absence of the falx in R.D.B.

The problem now arose as to how to cover the denuded brains, which had no dura mater. Polyethylene film was used for this purpose; it was sutured to the dural edge of R. L. B.'s brain and to the dural and/or subcutaneous tissues over R. D. B.'s brain. The blood loss had been so great and the operation had taken such a long time that it was felt unwise to consider reflecting the scalp flaps and placing them in position on top of the polyethylene film, for this would have meant more hours of operating time and more loss of blood that might not have been withstood. It had originally been planned to put polyethylene plates in place at this time, but the molding of these plates and their anchoring into the wound would again have been too onerous a burden, so this, too, was omitted and we were content to use sterile aluminum foil to cover the top of each head before putting on dry dressings and sterile bandages. The aluminum foil was easily molded, could be sewed, and was believed to be mildly bacteriostatic. The entire procedure required 12½ hours. R. D. B. received 2,500 cc. of blood and R. L. B. 3,500 cc. during procedure.

After separation, R. D. B. cried spontaneously; R. L. B. showed attempts at crying while the endotracheal tube was still in place. A small catheter placed in the tube revealed an obstruction. The quick removal of the tube and tracheobronchial aspiration showed that the accumulation secretions had become rubber-like, blocking the airway. After this resuscitative procedure, the baby cried weakly.

Course of R. D. B.—At the time of separation when it was necessary to separate the venous plexus, there was a sudden loss of blood that resulted in a severe cardiovascular collapse in R. L. B., so that no pulse, blood pressure, or heart sounds were detectable. The very rapid administration of oxygen by pressure on the breathing bag, positive pressure on the thorax, and rapid intravenous infusion of blood restored essentially normal cardiovascular function. He did not respond to painful stimuli. About eight hours after operation, there was marked irregularity of rate and depth of respiration, with retraction of the suprasternal and infrasternal regions. Secretions from the hypopharynx were aspirated easily, with the patient in an atmosphere rich in oxygen and moisture, but signs of right upper pulmonary atelectasis appeared. Although it was considered probable that much of the respiratory difficulty might be due to central nervous system derangement, tracheotomy was done by Dr. Cecil Riggs of the department of otolaryngology, to provide as open an airway as possible. Periodic breathing of the Biot type appeared, however, indicating a central nervous system cause for the respiratory difficulty. Accordingly, the head dressings were removed, when it was seen that the swelling and engorgement of the cerebrum seen during the operation had progressed. Relief of pressure by removing the artificial coverings of the brain brought immediate improvement in breathing. The tachycardia observed during the Biot breathing became slower.

With the long exposure of the brain, contamination and possible infection were anticipated, so penicillin and streptomycin were given intramuscularly. Organisms sensitive to these antibiotic agents were suppressed, but an infection with Pseudomonas aeruginosa was detected on the fourth postoperative day. This was controlled by daily local applications of 2½% polymyxin B to the surface of the brain and by intramuscular injections of 2 mg. per kilogram of body weight per day. No evidence of systemic toxicity was discovered, although the antibiotic was given until his death 34 days after separation. By this time, the surface infection of the brain was completely controlled. Staphylococcic organisms were controlled by intermittent administration of aureomycin, oxytetracycline (Terramycin), and erythromycin. Eleven days after operation, signs of diffuse bronchopneumonia appeared, with marked expiratory difficulty and very tenacious secretions. In order to liquefy these, water was nebulized over the tracheotomy tube. Since high humidity alone proved insufficient, a solution of trypsin (Tryptar) was given as an aerosol through the nebulizer (20,000 to 50,000 units of trypsin in 2 to 3 cc. of diluent at ph 7.4 every six to eight hours. On several occasions, Alevaire (a solution of glycerine, sodium bicarbonate, and a detergent, Triton WR-1339, in distilled water) was used in a similar manner. Marked liquefaction of the secretions resulted, permitting their aspiration and resulting in marked improvement in respiration. No evident signs of toxicity to the drug were noted. The signs of bronchopneumonia subsided. During the survival period, the infant remained comatose and exhibited signs of decorticate rigidity. Parenteral fluid therapy was given for the first few postoperative days, and thereafter nutrition was maintained by feedings through a no. 19 polyethylene nasogastric tube. Up to 4,500 calories daily were necessary. During the last week of life, there were marked variations in rectal temperature (108 F to 94 F), the peaks not responding to antipyretic measures. Respiratory irregularities of central nervous system origin appeared again on Jan. 19, 1953, and he died on Jan. 20, 1953.

Course of R. D. B.—Immediately after the separation, R. D. B. cried and moved all extremities. He took fluids by mouth the following day and responded to familiar persons. He was kept in oxygen with supersaturated humidity to minimize the effects of the prolonged period of intubation. Supplementary parenteral fluids and antibiotics were given as with R. L. B. On the fourth postoperative day, he was irritable and refused oral feedings. There was an odor from the head dressing characteristic of a Ps. aeruginosa infection, so the dressings were removed, and the surface infection which was found was treated with polymixin B in the same manner and dose as in R. L. B. The thick tenacious exudate typical of infection with this organism gradually subsided. It had not completely disappeared by Dec. 30, when the clinical status of the patients was improved sufficiently to permit proceeding with the plastic surgery (fig. 6). On this day, the scalp flap (fig. 6, part 1) was reelevated and transferred to cover the posterior half of the exposed intracranial structures (fig. 6, parts 2 through 5). The terminal end of the flap was turned to cover part of the anterior defect. All of this flap grew well except for a short segment along the distal edge. This ultimately was trimmed off. After the flap was transferred, the donor site from which it was taken was covered with a large autogenous split-skin graft taken from his back (fig. 6, parts 6 through 8).

On Jan. 17, 1953, the base of the pedicle in the occipital area was divided so as to stimulate additional return circulation from the opposite end of the transplanted flap (fig. 6, part 9). On Feb. 10, the proximal end of the flap was completely detached from the occipital area and transferred forward to cover nearly all of the remaining open defect (fig. 6, parts 10 through 12). Donor sites were covered in each case by split-thickness grafts, some of which had to be revised later.

On March 11, the "dog ear" in the flap was divided in its central portion. The anterior part of the flap was reelevated until it could be shifted anteriorly without tension to cover the balance of the open cranium. The excess "dog ear" was trimmed off and its edges sutured. By this time, the infection was not apparent. This twin, too, showed no signs of toxicity from the antibiotics.

Several days after the separation, when there was more spontaneous activity, it became apparent that there was a left hemiparesis and left astereognosis. Although he was able to hold objects when he looked at them, he did not know what to do with them if his eyes were turned away, nor did he place his extremities properly if he did not see them. The hemiparesis disappeared within the first month, but the astereognosis still continues, although less marked than before. There are no hyperactive stretch reflexes on the left, nor is there any loss of common sensibility. There are intermittent Babinski signs on both sides, which are considered to be normal for his age.

Before the separation, the neuromuscular development of the twins was considered normal. This was assessed with difficulty because of the peculiar nature of the junction of the heads, which undoubtedly interfered with the development of head control, tonic neck reflexes, and the ability to sit and stand. Both had normal infant jargon. During the three months that followed separation, R. D. B. showed only a slow progression of

development. This is attributed to the trauma of separation, debility, infection, and repeated operations that took place during this period. Since the head covering has been completed, he has shown a considerable advance in development and improvement in his general physical state. He has had a considerable amount of occupational and physical therapy, which has contributed to this improvement. He can now sit alone, but cannot pull himself into the sitting position. He has good control of his head and good coordination of all extremities, and his jargon has increased in amount and in intelligibility. He is alert, responds to favored personnel, and makes attempts to feed himself. The hip flexors (which were tight, presumably owing to lack of standing) have become normal with physical therapy. It is difficult to assess the degree of development in all spheres because of the many factors, biological, traumatic, and psychological, that have affected his present state.

There is still no solid protection for the brain, and the solution of this problem is now under active consideration. We are reluctant to use any foreign material over such a large surface of dura mater and under skin flaps, because of the hazards accompanying buried foreign bodies. Autogenous bone grafts appear to offer the best replacement for the calvarium that never developed, but the extensiveness of the defect make accomplishment of closure by this means difficult.

All the professional and technical skills have basically one objective—to permit this baby to grow and develop as a happy, effective human being. His handicap—like other handicaps—need not prevent him from fulfilling this goal. It has been necessary throughout, therefore, to provide for him as well as his family an understanding and comfortable environment. Without such an environment—and without the help of his parents and our help to them in understanding his problems—the boy's development might not have proceeded so well. The future planning must involve most careful attention to his emotional and social development. This will consist of his parents' greater and greater participation in his care as his physical problems permit, continued medical and surgical efforts to correct his physical difficulties with as little pain and discomfort as possible, and long-term planning to assure stimulating educational opportunities that are compatible with his capacities. These provisions, associated with increasing understanding of all handicapped children by the public, will provide the best assurance that this boy will have the opportunities that should come to all children—that of the fulfillment of his greatest potentialities as a human being.

CHOICE OF A CORONARY VASODILATOR DRUG IN CLINICAL PRACTICE

EVALUATION OF EFFECTS BY ELECTROCARDIOGRAPHIC TESTS

Henry I. Russek, M.D., Karl F. Urbach, M.D., Alexander A. Doerner, M. D.
and
Burton L. Zohman, M.D., Staten Island, N. Y.

Each year new drugs are introduced that are alleged to have coronary vasodilator action. After an initial enthusiastic endorsement, most of these agents fall into disrepute or lose popularity because of the uncertainty arising from conflicting claims. Frequently, the clinical value of a coronary vasodilator drug has been estimated from its pharmacological action in animals or from its performance in uncontrolled studies in human disease; less often it has been appraised from carefully controlled analyses of the subjective sensation of pain in patients with angina pectoris. Some attempts to determine the effect of drugs on the severity and frequency of anginal attacks occurring spontaneously or induced by exercise have successfully removed or minimized the element of bias; but even the best of these methods employing the double blind technique with placebo and test materials have left much to be desired. Such procedures would be acceptable for assaying the vasodilator potency of drugs, if pain represented a definite entity and reflected a fairly constant degree of coronary insufficiency in each patient. Obviously, this is not the case. Pain is of infinite variability and to date has not been accurately quantitated in man either subjectively or objectively. Furthermore, even if such precise measurement were possible, pain could not reliably reflect the status of the coronary circulation or the degree of myocardial ischemia. In our laboratory, for example, patients who show constant electrocardiographic alterations with each performance of a standard exercise test under carefully controlled conditions have experienced no distress on some occasions and appreciable pain on others. Conversely, as Dock[1] has pointed out "a minute ischemic area in the myocardium may cause as severe discomfort as ischemia of a whole ventricle." By such methods of evaluation, drugs that only elevate the threshold for pain might be erroneously labelled as coronary vasodilator agents. A more accurate index of coronary insufficiency than that afforded by the subjective sensation of pain alone is, therefore, needed if rational therapy by means of drugs is to be established in angina pectoris.

With this need in mind, we attempted to record and compare the ability of specific agents to modify the electrocardiographic response to standard exercise (Master

two-step test) in carefully selected persons.[2] To have validity such investigation must include only those patients with coronary disease who exhibit, on repeated testing under identical conditions, a relatively constant positive response to a given amount of exercise. The difficulty in obtaining patients suitable for such study can be estimated from a four year experience in screening over 3,000 patients with coronary artery disease by means of a two-step exercise electrocardiographic test. Of this number, only 52 patients qualified as fulfilling the criteria. In these patients, it was found that appreciable periods exist during which the electrocardiographic alterations evoked by standard exercise recur in almost identical fashion with each performance of the test. Even after weeks or months of observation, it was often necessary only to add or subtract several ascents and descents of the two-step staircase to obtain new controls for further test comparisons. By such adjustments, the inevitable changes attending the natural course of the disease did not hinder continued use of most of these test subjects for bioassay of vasodilator drugs. In this manner, as many as 200 exercise tests were carried out in one patient over a four year period.

MATERIAL AND METHOD

Fifty of the patients in this series were men between the ages of 32 to 77 years. Two were women, 49 and 52 years of age, respectively. Seven of the 52 patients had sustained previous myocardial infarction; and 30 presented classic symptoms of angina pectoris. Arterial hypertension was present in 20 of the 52 subjects. In all patients included in this series, the control response to exercise remained constant when recorded from day to day and, in addition, could be favorably modified by the sublingual administration of therapeutic doses of glyceryl trinitrate (nitroglycerin) just before the test. By establishing this prerequisite, it was felt that a basis for comparison could be obtained between the effect of the potent coronary vasodilator glyceryl trinitrate and that of other agents with unknown or undefined action. Under informal conditions with reassurance, demonstration, and explanation designed to allay the patient's anxiety, these tests were carried out under identical environmental conditions at the same time each day and by the same observers. In most instances, only one test was performed in any 24 hour interval. Each drug was tested three to six times in every patient. The following drugs (see table) were studied: glyceryl trinitrate, papaverine hydrochloride, ethyl alcohol (in the form of scotch or rye whiskey), aminophylline, Roniacol (beta-pyridyl-carbinol tartrate), tolazoline (Priscoline) hydrochloride, tetraethylammonium chloride, octyl nitrite, dioxyline (Paveril) phosphate, visammin (khellin), heparin, bishydroxycoumarin (Dicumarol), pentaerythritol (Peritrate) tetranitrate, and morphine.

Analysis of Results of Various Drugs in Fifty-Two Patients

Drug	Dosage	No. of Tests	No. of Patients	Good Response (Patients)
Glyceryl trinitrate	1/100-1/150 grain	268	52	52
Papaverine	1-2 grains I.V.	38	10	7
	3-8 grains orally	71	14	7
	1.5 grains orally	36	12	0
Ethyl alcohol	1-2 oz.	62	12	0
Pentaerythritol (Peritrate) tetranitrate	10-20 mg.	64	12	8
Aminophylline	7.5 grains I.V.	28	8	1
	6 grains orally	18	6	0
Roniacol (beta-pyridyl-carbinol tartrate)	100 mg. orally	33	8	0
Visammin (khellin)	200 mg. I.M. or orally	41	7	0
Octyl nitrite	1-4 inhalations	92	15	3
Tolazoline (Priscoline) hydrochloride	25-50 mg. I.M. or orally	30	6	0
Tetraethylammonium chloride	300-500 mg. I.M.	24	8	0
Dioxyline (Paveril)	200-500 mg. orally	52	10	2
Heparin	50-100 mg. I.V.	110	18	0
Bishydroxycoumarin (Dicumarol)	200 mg.	21	6	0
Morphine	¼ grain subcutaneously	9	6	0

RESULTS

Glyceryl Trinitrate.—The 52 patients in this series were tested repeatedly with glyceryl trinitrate, and, on every occasion, a strikingly favorable effect on the response to exercise as recorded electrocardiographically was observed (fig. 1 to 3). A normal exercise response was obtained in 39 of the 52 patients when 1/150 to 1/100 grain (0.4 to 0.6 mg.) of glyceryl trinitrate was administered sublingually five minutes prior to commencement of the test. In the remaining 13, although a completely negative record was not obtained after administration of glyceryl trinitrate, significant improvement in the postexercise electrocardiographic patterns was observed in each instance.

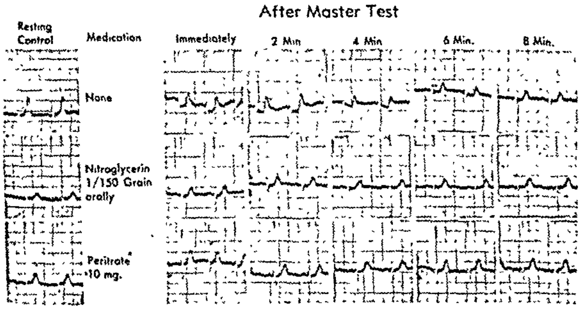
Fig. 2.—Master test responses (lead V_4) in a patient with coronary insufficiency with and without the administration of drugs.

Papaverine Hydrochloride.—Papaverine was administered in doses of 1 to 2 grains (0.06 to 0.12 gm.) intravenously or 1.5 to 8 grains (0.10 to 0.518 gm.) orally to 14 patients in this series. Intravenous administration five minutes before exercise was found effective in 7 out of 10 patients as shown by completely normal responses or improved electrocardiographic patterns as compared to controls (fig. 1 and 2). Large oral doses of papaverine, 3 to 8 grains (0.194 to 0.518 gm.), gave similarly favorable results in 7 of 14 patients who were tested from 60 to 90 minutes after its administration. In contrast, usual therapeutic doses of papaverine showed negligible effect on the electrocardiographic response to standard exercise.

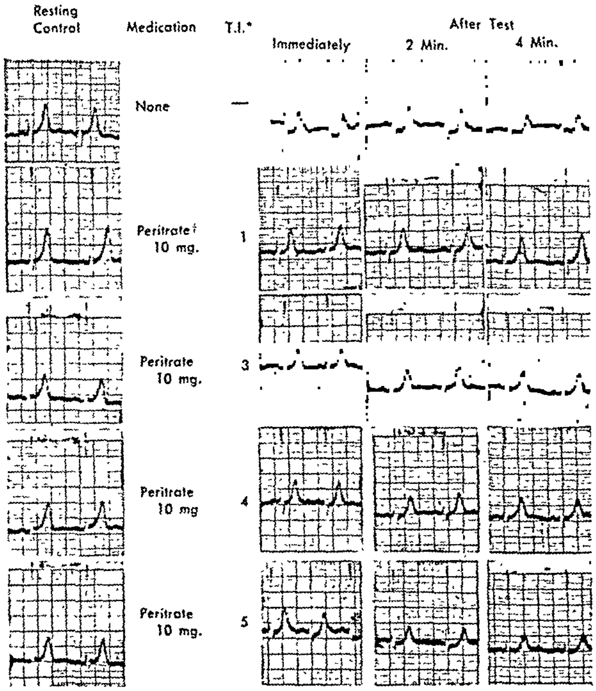


*Pentaerythritol tetranitrate

Fig. 3.—Effect of glyceryl trinitrate and pentaerythritol tetranitrate respectively on the response to the Master test (lead V_4) in a patient with coronary insufficiency. Glyceryl trinitrate was given five minutes before the test, pentaerythritol tetranitrate one hour before.

Ethyl Alcohol.—Twelve patients were given ethyl alcohol in the form of scotch or rye whiskey (1 to 2 ounces) 5 to 20 minutes before exercise. Although 62 tests were performed with this drug, not a single instance was noted in which the electrocardiographic response was favorably influenced by its administration (fig. 1 and 2). In striking contrast, it was also found that ethyl alcohol prevented or reduced anginal pain in all seven patients in this group in whom this symptom was evoked during control tests.

Pentaerythritol Tetranitrate.—In a dose of 10 to 20 mg., pentaerythritol tetranitrate was found to exert a marked modifying influence on the electrocardiographic response to standard exercise in 8 of 12 patients tested. In all of the patients showing favorable response, the results were comparable to those obtained with glyceryl trinitrate, but the duration of action was considerably more prolonged. Thus, with pentaerythritol tetranitrate, an improved response could be elicited as long as four to five hours after administration of the drug (fig. 3 and 4).



* Hours between medication and test.
† Pentaerythritol tetranitrate.

Fig. 4.—Master test responses in a patient with coronary insufficiency after a single dose of 10 mg. of pentaerythritol tetranitrate; normal response obtained as long as four hours after administration of the drug.

Other Drugs.—Aminophylline in the dose of 7½ grains (0.5 gm.) intravenously or 6 grains (0.4 gm.) orally and Roniacol in a dosage of 100 mg. orally were both found to have slight or insignificant effect. Even in massive doses, visammin, 200 mg. administered intramuscularly or orally, failed to alter favorably the electrocardiographic response in all patients tested. Octyl nitrite by inhalation was at best as effective as 1/300 grain

(0.2 mg.) of glyceryl trinitrate. Tolazoline hydrochloride in 25 to 50 mg. doses intramuscularly or orally and tetraethylammonium chloride in 300 to 500 mg. doses intramuscularly showed either no modifying effect or an adverse influence on the response to exercise. Dioxyline phosphate in amounts similar to those employed with papaverine did not give comparable results. Dioxyline phosphate appeared to be a much less potent drug than papaverine according to this method of testing. Heparin in recommended doses (50 to 100 mg. administered intravenously once or twice a week) did not exert a significant effect on the electrocardiographic response to standard exercise in any of the patients tested. Bishydroxycoumarin in therapeutic dosage was also without demonstrable value. Morphine, like ethyl alcohol, prevented the onset of pain but failed to exert a modifying influence on the electrocardiographic response to standard exercise.

COMMENT

The findings of this investigation suggest that only 3 of the 14 drugs studied are worthy of continued clinical use as vasodilators in the management of angina pectoris or other states of coronary insufficiency. These drugs are glyceryl trinitrate, papaverine, and pentaerythritol tetranitrate. Glyceryl trinitrate remains the drug of choice for treatment of the acute attack and for prophylaxis just prior to contemplated exertion. For prolonged protection, pentaerythritol tetranitrate (10 to 20 mg., three times a day) appears to excel all other drugs tested. It is superior to papaverine because of the higher proportion of persons influenced favorably, the greater duration of action, and the expense of the latter in effective dosage. When papaverine is prescribed in cases of coronary disease, it would seem that a minimum oral dosage of 3 grains (0.2 gm.) three or four times a day is indicated. Considerably smaller doses, however, are effective parenterally.

The failure of ethyl alcohol to influence the electrocardiographic response to exercise in all patients studied appears to indicate that this agent is without coronary vasodilator action. Alcohol has long been known to be a depressant of the central nervous system capable of decreasing anxiety and promoting a sense of well-being. Since the administration of ethyl alcohol prophylactically may not only create a false sense of physical fitness but remove the protection afforded by angina, the danger of its employment prior to contemplated exertion should be recognized. Consequently, although it effectively relieves anginal pain through a sedative action, the fact that underlying myocardial anoxia remains unaltered by its use must not be overlooked. In these respects, morphine was found to act similarly. Ethyl alcohol appears to have value as a sedative for some patients with coronary disease and seems best taken during the leisurely hours at the end of the day. For the anginal attack, however, it must be considered a poor substitute for glyceryl trinitrate since like morphine it is completely ineffective in preventing or correcting coronary insufficiency.

As Starr [3] has pointed out, generalized vasodilatation cannot be produced without a concomitant increase in blood volume. Since rapid increments of blood volume are not possible, the blood needed to fill vessels the diameter of which has rapidly increased must be withdrawn from other vessels the diameter of which must diminish correspondingly. Vasodilatation in some vascular areas causes reflex vasoconstriction in others so that an exchange of blood flow by a borrowing-lending process would seem operative. With this concept in mind, it is perplexing to find that different authors advocate the same drug for augmenting cerebral, coronary, renal, and peripheral blood flow. The fact that ethyl alcohol causes dilatation of skin vessels and draws blood to the surface of the body would seem to suggest that it may fail to augment coronary blood flow. This was actually substantiated by our studies. Similarly, the recognized value of tolazoline hydrochloride as a dilator of peripheral vessels should raise the question of whether or not this drug might actually decrease coronary blood flow. Several of our observations with this drug have at least pointed in that direction.

Heparin and bishydroxycoumarin have been considered of value by Gilbert and Nalefski [4] in the treatment of coronary disease, because of an alleged action of these drugs in increasing coronary blood flow. Similarly, Graham and associates [5] have reported marked relief of symptoms in patients with angina pectoris who had weekly or biweekly injections of 50 to 100 mg. of heparin. The improvement, however, was attributed by these authors to the profound effect of heparin on lipoprotein metabolism, rather than to a vasodilator or antithrombotic action. Our studies [2b] with these drugs have shown no demonstrable effect on the electrocardiographic response to standard exercise; moreover, we have been unable to confirm the striking subjective improvement in anginal symptoms reported by others from the use of heparin.

SUMMARY AND CONCLUSIONS

Evaluation of vasodilator drugs in the treatment of coronary disease presents a difficult problem because of the lack of objective methods of study, the inapplicability of animal observations to man, the element of subconscious bias, and the inaccuracy of clinical estimates of coronary reserve and myocardial anoxia that are based on the symptom of pain. We attempted to avoid some of these pitfalls by recording and comparing the ability of specific agents to modify the electrocardiographic response to standard exercise (Master two-step test) in carefully selected cases.

The findings seem to justify the following conclusions: 1. Glyceryl trinitrate (nitroglycerin) in therapeutic doses exerts a strikingly favorable effect on the response to exercise as recorded electrocardiographically. 2. Papaverine in the dosage of 1 to 2 grains (0.065 to 0.12 gm.) intravenously or 3 to 8 grains (0.194 to 0.518 gm.) orally is effective in some patients in decreasing or abolishing the abnormal electrocardiographic response to standard exercise. Such benefit was not, however, observed with usual therapeutic doses of the drug. 3. Of all the agents tested, pentaerythritol (Peritrate) tetranitrate appears to be the most effective drug currently available for prolonged prophylactic therapy in angina pectoris. A 10 to 20 mg. dose affords protection for four to five hours, as judged from the two-step test in the majority of patients studied. 4. Aminophylline, Roniacol (beta-pyridyl-carbinol tartrate), tolazoline (Priscoline) hydrochloride, tetraethylammonium chloride, octyl nitrite, dioxyline (Paveril) phosphate, visammin (khellin), heparin, and bishydroxycoumarin (Dicumarol) appeared unimpressive when evaluated according to this method. 5. Ethyl alcohol, in 1 to 2 ounce amounts, consistently fails to influence the electrocardiographic response to exercise, although it does prevent or reduce the severity of anginal pain. Alcohol should, therefore, be recognized as a rapidly acting sedative and should no longer be regarded as a coronary vasodilator drug. Morphine is identical to alcohol in its effect on pain and in its failure to modify the exercise response. 6. Of the drugs tested, only glyceryl trinitrate, papaverine, and pentaerythritol tetranitrate appear worthy of continued clinical use as vasodilators in the management of angina pectoris.

CLINICAL NOTES

CORONARY EMBOLISM

John T. O. Cheng, M.D.
William J. Cahill, M.D.
and
Edmund F. Foley, M.D., Chicago

Coronary embolism is a very rare occurrence. The first case was reported by Virchow[1] in 1856. Saphir,[2] in 1933, collected 16 cases of coronary embolism from the literature and reported 3 that he had observed himself. In 1941, Hamman[3] was able to refer to 40 cases, 30 from the literature and 10 from records of the Johns Hopkins hospital. In 1950, Moragues, Bawell, and Shrader,[4] after reviewing the literature, were able to refer to 45 cases and reported one of their own. Since then, individual cases have been reported by Mussafia,[5] Rodario,[6] Facquet,[7] Ravera,[8] Aguiar,[9] Glushien,[10] and Walker.[11] A total of 53 cases of coronary embolism have been reported in the literature to date. Among them only three were diagnosed during life. We present a case of coronary embolism in which the diagnosis was made before death and confirmed at autopsy.

REPORT OF A CASE

A 21-year-old white woman, gravida 3 and para 2, first entered the hospital on Dec. 12, 1950. She was admitted to the surgical obstetric service complaining of pain in the right flank when the fetus moved and also of easy fatigability. She stated that at 10 years of age she had "St. Vitus' dance" that compelled her to stay in bed for two years because she was unable to walk. After those two years, she resumed her normal activities without any difficulties. In June, 1948, she spontaneously delivered her first child, at which time her physician told her that she had "heart trouble." Her second spontaneous delivery in August, 1949, of a 6 lb. 10 oz. (3,005 gm.) boy was uneventful. After this delivery, the patient's tolerance to exercise gradually decreased. She stated that she became short of breath when climbing stairs, although she complained of no dyspnea at rest, orthopnea, ankle edema, or any other cardiac symptoms. She became pregnant for the third time and was well until two weeks prior to her admission to the hospital, at which time there developed an increase in exertional dyspnea and pain associated with fetal movement. The patient had been receiving no prenatal care, and she was not taking any cardiac medication. The rest of her history was noncontributory except that her mother died of rheumatic heart disease at the age of 31.

Physical examination on admission revealed a young woman who did not appear acutely ill. Her temperature was 98.2 F; pulse 104 per minute; respirations 20 per minute; and blood pressure 105/75 mm. Hg. There was a slight malar flush. Lungs showed moist basilar rales bilaterally. Sinus rhythm was regular. Apical impulse was in the fifth interspace in anterior axillary line. A systolic, blowing murmur and a mid-diastolic rumble with a palpable thrill were found at the apex. A pulmonic systolic murmur with a reduplicated second tone was also heard. P_2 was louder than A_2. The liver was enlarged and extended 3 cm. below the costal margin. Hepatojugular reflex was negative. The uterus contained a 36 to 38-week-old fetus. The legs were not edematous.

A chest film showed the heart to be increased in transverse diameter, with fulness of the pulmonary artery segment. There was also a suggestive double density overlying the heart that was thought to be due to left auricular enlargement. Definite congestive changes in both lungs were noted, although effusion was not present. Urinalysis showed nothing abnormal, and reaction to a Kahn test was negative. An electrocardiogram revealed a right axis deviation and broad, notched, flat-topped P waves in leads 1 and 2. A diagnosis of rheumatic heart disease, mitral stenosis, and regurgitation with decompensation was made.

While in the hospital, the patient was treated with digitalis, ammonium chloride, and meralluride sodium solution (Mercuhydrin). She was kept at absolute bed rest and maintained on a low salt diet. Under this management, compensation was achieved, and, on Jan. 3, 1951, the patient delivered spontaneously. Tubal ligation was performed two days after the delivery. Compensation was good throughout both procedures, and the patient was discharged on Jan. 15, 1951, in good condition.

The patient entered a women's medical ward of the same hospital on Aug. 28, 1952, at 9:25 a. m. as a case of acute cardiac emergency. During the preceding 19 months, the patient had been well, had cared for her family, and had no symptoms of decompensation in spite of the fact that she was taking no cardiac medicaments. She was perfectly well until an hour and a half before admission, when dyspnea, cyanosis,

severe palpitation, and respiratory distress developed. After being seen by a local physician, she was transported to the hospital in a pole ambulance with oxygen.

Physical examination showed an apprehensive, conscious white woman in acute cardiorespiratory distress. She was cyanotic and dsypneic, and her skin was cold and moist. Blood pressure was 80/10 mm. Hg; temperature 98.5 F; respirations 40 per minute; and pulse thready and irregular, about 48 to 50 per minute. Neck veins were engorged. Lungs were full of inspiratory and expiratory rales and coarse rhonchi. The patient was frothing at the mouth. Apical heart rate was 180 per minute and irregular; it was too rapid to detect any adventitious sounds. A marked precordial heave was noted. The abdomen was soft and not distended. The liver was felt 3 cm. below the costal margin; its edge was round; and the organ was only slightly tender. The extremities were cold and clammy but not edematous. Urinalysis revealed a specific gravity of 1.014, no albumin, no sugar, and 1 to 2 white blood cells per high power field.

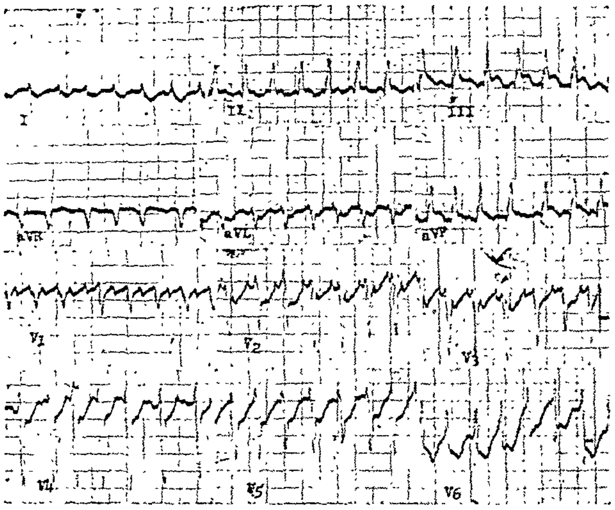

Fig. 1.—Standard limb leads, unipolar limb leads, and unipolar precordial leads showing an acute posterior myocardial infarction.

The patient was given 95% alcohol aerosol in oxygen immediately on admission and, also, aminophylline, 7 grains (0.45 gm.), and digitalis (Digalen), 3 grains (0.19 gm.), intravenously.

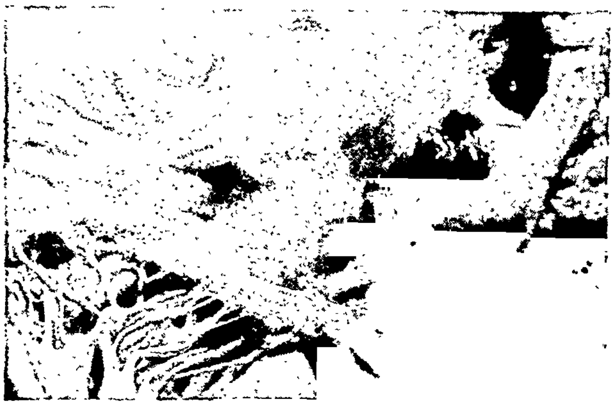

Fig. 2.—Thickened and deformed cusps of the mitral valve and the mural thrombus in the left auricle.

An electrocardiogram was made. It showed auricular fibrillation, with a rapid ventricular response, prominent Q waves in leads 2, 3, and aVF, elevated S-T segments in leads 2, 3, and aVF, and reciprocal depression of S-T segments in leads 1, aVL, V_2, V_3, V_4, V_5, and V_6 indicative of an acute posterior myocardial infarction (fig. 1). A diagnosis was made of recent myocardial infarction of the posterior wall caused by coronary embolism resulting from a thrombus formed in a fibrillating left auricle in a rheumatic heart with mitral stenosis.

The patient's course was rapidly downhill. She was given another 3 grains of digitalis intravenously. Heart tones became imperceptible. An intracardiac injection of 2 cc. of 1:1,000 solution of epinephrine reinstituted an irregular cardiac beat that persisted for two to three minutes until apnea began and then faded. Despite all therapy, the patient died at 10:30 a. m. on Aug. 28, 1952.

At autopsy, the body was cyanotic, and the chest was somewhat emphysematous. Each pleural cavity contained approximately 2,000 cc. of serous fluid, and the pericardial cavity contained 80 cc. of serous fluid.

The heart weighed 350 gm. and was markedly enlarged. Apex and base diameters were 12 cm., and transverse diameter at the base was 10 cm. The epicardium was smooth and glistening, and there was a normal amount of subepicardial fat tissue. The myocardium of the right ventricle was 3 mm. thick and that of left ventricle 14 mm. The tricuspid valve measured 13 cm. in circumference and was not abnormal. Pulmonic valves measured 8 cm. in circumference and were normal. Mitral valve measured 5 cm. in circumference. The valve leaflets were markedly thickened, with shortening and thickening of papillary muscles and chordae tendinae (fig. 2). The aortic valve measured 8 cm.; the cusps were smooth and normal. There was little atherosclerosis of the aorta. The left auricle was greatly dilated and hypertrophied. In the left auricular appendage, a thrombus was noted (fig. 2). The coronary vessels showed no arteriosclerotic changes. In the left circumflex branch of the left coronary artery, an embolus measuring 4 by 2 by 2 mm. was seen that completely occluded the lumen of this vessel (fig. 3). The embolus was laminated and was not adherent to the vessel wall. The myocardium of the posterior wall of the heart showed a large area of tissue that appeared paler and drier than normal.

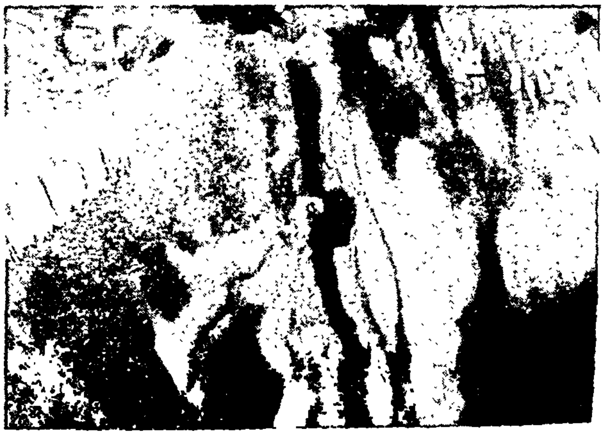

Fig. 3.—Embolus in the circumflex branch of the left coronary artery.

Both lungs weighed 1,300 gm. and were heavier than normal. Cut section revealed a large amount of frothy, sanguinous fluid. The pulmonary arteries were clear of thrombi. The liver weighed 1,600 cm., showed considerable blunting of the inferior margin, and was severely congested. The spleen weighed 300 gm. and was markedly congested. The only finding in the esophagus, stomach, and small and large bowels was congested mucosal surfaces. The adrenal glands were normal. Kidneys weighed 300 gm. The capsule stripped with ease and revealed a smooth cortical surface; a cut section showed evidence of congestion. The uterus was that of a multipara and was normal. Both tubes were cut and ligated in the isthmic portion. The left ovary contained a corpus luteum. The brain weighed 1,000 gm. and was normal.

Microscopic section from the area of infarction in the left ventricle revealed fragmentation of the myocardium. The nuclei of some of the fibers were pyknotic; the cross striations, however, were still preserved. The interstitial connective tissue was edematous. The capillaries and thin-walled veins were markedly engorged.

COMMENT

Embolic occlusion of the coronary arteries is a rare occurrence. The infrequency of this condition has been attributed to (*a*) the difference between the caliber of the aorta and that of the coronary, (*b*) the situation of the coronary vessels at the root of the aorta, (*c*) the right angle emergence of the coronary arteries, (*d*) the bulk and swiftness of the blood current in this portion of the aorta, and (*e*) the fact that the major part of coronary filling occurs during diastole. In reviewing the literature, there appear to be eight possible sources of emboli that may occlude the coronary arteries. The sources of emboli in the cases reviewed in the literature are listed in the table. In our patient, the embolus originated in the left auricular appendage and was sterile.

According to Garvin,[12] in 25% of all cases of heart disease, there are mural thrombi in the left side of the heart, which predispose it to the occurrence of embolism. Small emboli cause no conspicuous symptoms. Only when they are large enough to occlude big arteries or lodge in organs in which even relatively small infarcts produce grave symptoms does their presence become noticeable. The two organs most sensitive to infarction are the brain and the heart. In cardiac patients, evidence of cerebral embolism occurs commonly; coronary embolism occurs infrequently. When the peculiarities of the coronary circulation as previously enumerated are considered, infrequent occurrence of the latter is not remarkable.

Coronary occlusion due to embolism not only is a very rare occurrence but is rarely diagnosed during life. In only three [13] cases was the correct diagnosis made during life; all three were cases of bacterial endocarditis; in all three, the emboli were not sterile; and all three patients lived long enough to reveal distinctive clinical and electrocardiographic features.

Our case was unique in several respects. The embolus originated in a thrombus in left auricle, and bacterial endocarditis was not present. Both the thrombus and the embolus found in the coronary artery were sterile. The coronary embolism involved the circumflex branch of the left coronary, a site of occlusion by embolus hitherto not reported in the literature. Our patient lived only a little more than one hour, the shortest survival time among cases of coronary embolism that were correctly diagnosed before death.

We reconstructed the sequence of events in our case as follows. The enlargement of the left auricle followed mitral stenosis, and, as frequently happens, a thrombus formed in the cavity of left auricle, particularly in the appendage. Also, auricular fibrillation might have contributed to the formation of the auricular thrombus. From the thrombus in the left auricle came the embolus that lodged in the circumflex branch of the left coronary artery and that caused posterior myocardial infarction, acute left ventricular failure, and death. Although the myocardial infarction was evident grossly, we failed to demonstrate microscopically any definite necrosis of the myocardium in the infarcted area. Apparently the patient succumbed to the shock of acute occlusion of the coronary artery so soon that there was no time for tissue necrosis to become evident. In patients who die within 12 hours after a coronary occlusion, histological evidence of infarct in the heart may not be found.[14]

Although embolic occlusion of the coronary arteries is very uncommon, it is probably commoner than the few reports in the literature would indicate.[3] Hamman [3] conservatively estimated that from 1 to 2% of the cases of coronary occlusion are due to embolism; therefore, it is reasonable to assume that only a small number of the cases encountered at autopsy have been reported. When symptoms are minimal or atypical, coronary embolism is seldom suspected, and, if the patient survives, especially a person in the older age group, the diagnosis of occlusion caused by embolism cannot be proved. How often recovery occurs after coronary embolism is not known; however, probable instances have been reported.[15] It is predicted that the diagnosis of coronary embolism will be made more frequently as interest and familiarity incite more thorough investigation into each case of coronary occlusion, especially in young persons.

SUMMARY

A case of coronary embolism is reported, and a brief review of the literature is presented. This is the fourth case of coronary embolism that was diagnosed while the patient was alive. This patient had rheumatic heart disease, with mitral stenosis. Bacterial endocarditis was not present, and the source of the embolus was a left auricular thrombus. The occluded coronary artery was the left circumflex branch.

Fibrosis of the Sphincter of Oddi.—Obstruction to the free flow of bile through the lower end of the common duct due to lesions of the ampulla, the papilla of Vater, and the sphincter of Oddi occurs in a sufficient number of patients to make this a problem of real clinical importance. This obstruction can occur with or without pathologic conditions elsewhere in the extrahepatic biliary tract but is usually encountered in patients with gallstones. This intermittent or persistent obstruction is responsible for an appreciable number of the unsatisfactory results following cholecystectomy for cholelithiasis.—Richard B. Cattell, M.D., and Bentley P. Colcock, M.D., *Annals of Surgery*, June, 1953.

severe palpitation, and respiratory distress developed. After being seen by a local physician, she was transported to the hospital in a pole ambulance with oxygen.

Physical examination showed an apprehensive, conscious white woman in acute cardiorespiratory distress. She was cyanotic and dsypneic, and her skin was cold and moist. Blood pressure was 80/10 mm. Hg; temperature 98.5 F; respirations 40 per minute; and pulse thready and irregular, about 48 to 50 per minute. Neck veins were engorged. Lungs were full of inspiratory and expiratory rales and coarse rhonchi. The patient was frothing at the mouth. Apical heart rate was 180 per minute and irregular; it was too rapid to detect any adventitious sounds. A marked precordial heave was noted. The abdomen was soft and not distended. The liver was felt 3 cm. below the costal margin; its edge was round; and the organ was only slightly tender. The extremities were cold and clammy but not edematous. Urinalysis revealed a specific gravity of 1.014, no albumin, no sugar, and 1 to 2 white blood cells per high power field.

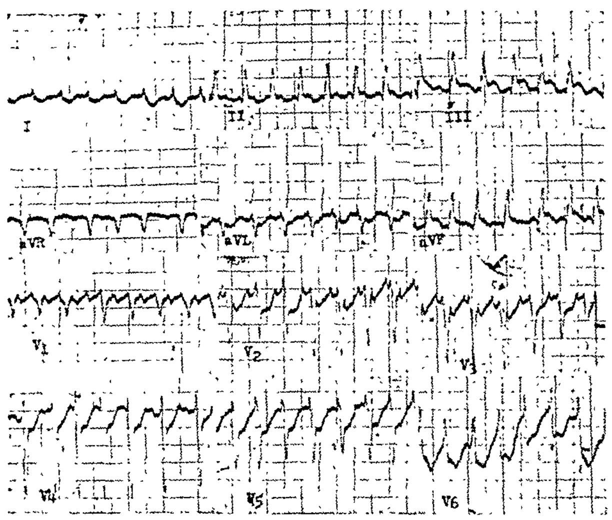

Fig. 1.—Standard limb leads, unipolar limb leads, and unipolar precordial leads showing an acute posterior myocardial infarction.

The patient was given 95% alcohol aerosol in oxygen immediately on admission and, also, aminophylline, 7 grains (0.45 gm.), and digitalis (Digalen), 3 grains (0.19 gm.), intravenously.

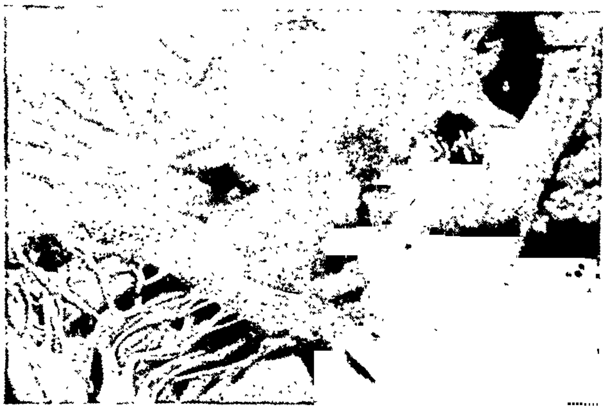

Fig. 2.—Thickened and deformed cusps of the mitral valve and the mural thrombus in the left auricle.

An electrocardiogram was made. It showed auricular fibrillation, with a rapid ventricular response, prominent Q waves in leads 2, 3, and aVF, elevated S-T segments in leads 2, 3, and aVF, and reciprocal depression of S-T segments in leads 1, aVL, V_2, V_3, V_4, V_6, and V_6 indicative of an acute posterior myocardial infarction (fig. 1). A diagnosis was made of recent myocardial infarction of the posterior wall caused by coronary embolism resulting from a thrombus formed in a fibrillating left auricle in a rheumatic heart with mitral stenosis.

The patient's course was rapidly downhill. She was given another 3 grains of digitalis intravenously. Heart tones became imperceptible. An intracardiac injection of 2 cc. of 1:1,000 solution of epinephrine reinstituted an irregular cardiac beat that persisted for two to three minutes until apnea began and then faded. Despite all therapy, the patient died at 10:30 a. m. on Aug. 28, 1952.

At autopsy, the body was cyanotic, and the chest was somewhat emphysematous. Each pleural cavity contained approximately 2,000 cc. of serous fluid, and the pericardial cavity contained 80 cc. of serous fluid.

The heart weighed 350 gm. and was markedly enlarged. Apex and base diameters were 12 cm., and transverse diameter at the base was 10 cm. The epicardium was smooth and glistening, and there was a normal amount of subepicardial fat tissue. The myocardium of the right ventricle was 3 mm. thick and that of left ventricle 14 mm. The tricuspid valve measured 13 cm. in circumference and was not abnormal. Pulmonic valves measured 8 cm. in circumference and were normal. Mitral valve measured 5 cm. in circumference. The valve leaflets were markedly thickened, with shortening and thickening of papillary muscles and chordae tendinae (fig. 2). The aortic valve measured 8 cm.; the cusps were smooth and normal. There was little atherosclerosis of the aorta. The left auricle was greatly dilated and hypertrophied. In the left auricular appendage, a thrombus was noted (fig. 2). The coronary vessels showed no arteriosclerotic changes. In the left circumflex branch of the left coronary artery, an embolus measuring 4 by 2 by 2 mm. was seen that completely occluded the lumen of this vessel (fig. 3). The embolus was laminated and was not adherent to the vessel wall. The myocardium of the posterior wall of the heart showed a large area of tissue that appeared paler and drier than normal.

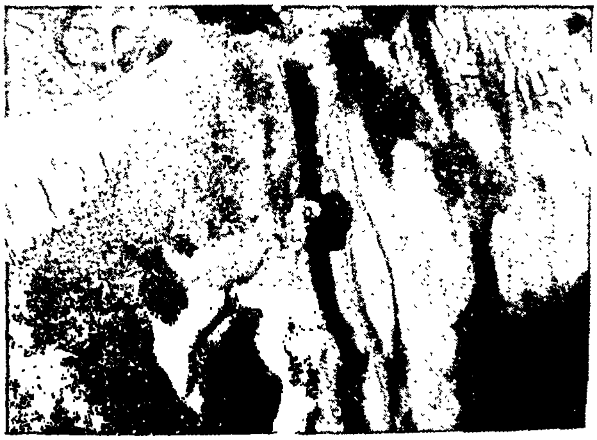

Fig. 3.—Embolus in the circumflex branch of the left coronary artery.

Both lungs weighed 1,300 gm. and were heavier than normal. Cut section revealed a large amount of frothy, sanguinous fluid. The pulmonary arteries were clear of thrombi. The liver weighed 1,600 cm., showed considerable blunting of the inferior margin, and was severely congested. The spleen weighed 300 gm. and was markedly congested. The only finding in the esophagus, stomach, and small and large bowels was congested mucosal surfaces. The adrenal glands were normal. Kidneys weighed 300 gm. The capsule stripped with ease and revealed a smooth cortical surface; a cut section showed evidence of congestion. The uterus was that of a multipara and was normal. Both tubes were cut and ligated in the isthmic portion. The left ovary contained a corpus luteum. The brain weighed 1,000 gm. and was normal.

Microscopic section from the area of infarction in the left ventricle revealed fragmentation of the myocardium. The nuclei of some of the fibers were pyknotic; the cross striations, however, were still preserved. The interstitial connective tissue was edematous. The capillaries and thin-walled veins were markedly engorged.

COMMENT

Embolic occlusion of the coronary arteries is a rare occurrence. The infrequency of this condition has been attributed to (*a*) the difference between the caliber of the aorta and that of the coronary, (*b*) the situation of the coronary vessels at the root of the aorta, (*c*) the right angle emergence of the coronary arteries, (*d*) the bulk and swiftness of the blood current in this portion of the aorta, and (*e*) the fact that the major part of coronary filling occurs during diastole. In reviewing the literature, there appear to be eight possible sources of emboli that may occlude the coronary arteries. The sources of emboli in the cases reviewed in the literature are listed in the table. In our patient, the embolus originated in the left auricular appendage and was sterile.

According to Garvin,[12] in 25% of all cases of heart disease, there are mural thrombi in the left side of the heart, which predispose it to the occurrence of embolism. Small emboli cause no conspicuous symptoms. Only when they are large enough to occlude big arteries or lodge in organs in which even relatively small infarcts produce grave symptoms does their presence become noticeable. The two organs most sensitive to infarction are the brain and the heart. In cardiac patients, evidence of cerebral embolism occurs commonly; coronary embolism occurs infrequently. When the peculiarities of the coronary circulation as previously enumerated are considered, infrequent occurrence of the latter is not remarkable.

Coronary occlusion due to embolism not only is a very rare occurrence but is rarely diagnosed during life. In only three [13] cases was the correct diagnosis made during life; all three were cases of bacterial endocarditis; in all three, the emboli were not sterile; and all three patients lived long enough to reveal distinctive clinical and electrocardiographic features.

Our case was unique in several respects. The embolus originated in a thrombus in left auricle, and bacterial endocarditis was not present. Both the thrombus and the embolus found in the coronary artery were sterile. The coronary embolism involved the circumflex branch of the left coronary, a site of occlusion by embolus hitherto not reported in the literature. Our patient lived only a little more than one hour, the shortest survival time among cases of coronary embolism that were correctly diagnosed before death.

We reconstructed the sequence of events in our case as follows. The enlargement of the left auricle followed mitral stenosis, and, as frequently happens, a thrombus formed in the cavity of left auricle, particularly in the appendage. Also, auricular fibrillation might have contributed to the formation of the auricular thrombus. From the thrombus in the left auricle came the embolus that lodged in the circumflex branch of the left coronary artery and that caused posterior myocardial infarction, acute left ventricular failure, and death. Although the myocardial infarction was evident grossly, we failed to demonstrate microscopically any definite necrosis of the myocardium in the infarcted area. Apparently the patient succumbed to the shock of acute occlusion of the coronary artery so soon that there was no time for tissue necrosis to become evident. In patients who die within 12 hours after a coronary occlusion, histological evidence of infarct in the heart may not be found.[14]

Although embolic occlusion of the coronary arteries is very uncommon, it is probably commoner than the few reports in the literature would indicate.[3] Hamman [3] conservatively estimated that from 1 to 2% of the cases of coronary occlusion are due to embolism; therefore, it is reasonable to assume that only a small number of the cases encountered at autopsy have been reported. When symptoms are minimal or atypical, coronary embolism is seldom suspected, and, if the patient survives, especially a person in the older age group, the diagnosis of occlusion caused by embolism cannot be proved. How often recovery occurs after coronary embolism is not known; however, probable instances have been reported.[15] It is predicted that the diagnosis of coronary embolism will be made more frequently as interest and familiarity incite more thorough investigation into each case of coronary occlusion, especially in young persons.

SUMMARY

A case of coronary embolism is reported, and a brief review of the literature is presented. This is the fourth case of coronary embolism that was diagnosed while the patient was alive. This patient had rheumatic heart disease, with mitral stenosis. Bacterial endocarditis was not present, and the source of the embolus was a left auricular thrombus. RUPTURE OF THE AORTIC VALVE

DISAPPEARING DIASTOLIC PRESSURE AS A DIAGNOSTIC SIGN

William B. Bean, M.D.
and
Martha C. Schmidt, M.D., Iowa City

Rupture of the aortic valve falls into two distinct clinical patterns; the first is rupture of the normal valve after some unusual stress or strain, particularly that of heavy lifting [1]; the other occurs when the valve is disorganized by bacterial endocarditis and erosion leads to rupture.[2] We wish to present an example of the second kind and emphasize a physical sign that may be helpful in detecting the aortic rupture clinically; namely, a sudden fall or complete disappearance of the diastolic blood pressure. Clinical signs of established aortic insufficiency are well known, but the observation of a normal diastolic pressure that declines significantly or disappears entirely has not been emphasized.

REPORT OF A CASE

L. C., a 44-year-old man, was admitted to the medical service of the University Hospitals because of chest pain and fever. Four weeks before admission he had a toothache and a swollen upper lip. Before he was able to consult a dentist, he was seized with a shaking chill, and his temperature rose to 104 F. His physician gave him 400,000 units of penicillin daily for a 10 day period. During this time the patient felt very much better, but, in spite of treatment, he had another chill and a fever of 105 F a week after the first chill. During the three week period after the first chill, he had four more similar episodes. He was then admitted to the local hospital. Laboratory studies revealed a hemoglobin level of 67%, red blood count of 4 million and sedimentation rate of 44 mm. per hour. Agglutination tests for typhoid and brucellosis were negative. Three days before he was transferred to the University Hospitals, the patient became orthopneic and had precordial pain that radiated to the back and increased on inspiration. The day before admission he noted a tender, red, swollen area approximately 3 cm. in diameter on the dorsum of the right foot. Sulfadiazine had been given along with penicillin.

On the patient's admission to the University Hospitals, physical examination revealed a seriously ill, orthopneic, dyspneic man who was perspiring freely. The neck veins were slightly engorged. There was decrease in resonance and tactile fremitus over the axilla on the left. Breath sounds were distant, with wheezes throughout both lungs and numerous inspiratory rales at both bases. The heart was enlarged, the left border extending to the anterior axillary line. A soft systolic and a grade 2 diastolic murmur were heard at the apex. There was an occasional extrasystole, but otherwise the heart rhythm was regular. The liver, slightly tender, was palpable two inches below the costal margin on the right. The erythematous area on the dorsum of the right foot was noted. Temperature was 104 F, pulse 104, respirations 20, and blood pressure was 120/58 mm. Hg. The history revealed that the patient had had *migratory arthritis* when he was 27 years old, and, 10 years prior to admission, he had been rejected for military duty because of "two leaky heart valves."

Laboratory studies revealed a hemoglobin of 8.8 gm. per 100 cc., red blood cell count of 3.2 million per cubic millimeter, and white blood cell count of 13,200 per cubic millimeter, with 74% granulocytes. Sedimentation rate was 64 mm. per hour. The urine had a specific gravity of 1.013 and 1+ albumin. The sediment contained numerous sulfadiazine crystals. A roentgenogram of the chest showed the heart to be enlarged both to the right and the left, with pulmonary vascular congestion. A small pleural effusion was seen in the left costophrenic angle. The electrocardiogram showed auricular fibrillation. Daily blood cultures were obtained, and all were reported subsequently as negative for micro-organisms. The patient was digitalized and put on a regimen of penicillin and oxytetracycline (Terramycin). On the *fifth hospital day, petechiae appeared on the soft palate*, and a grade 3 precordial friction rub appeared, obscuring the murmurs. The heart rate slowed, and the patient appeared better, but he continued to have a fever of 102 F daily. Oxytetracycline therapy was discontinued, and streptomycin therapy was begun. We suspected that active rheumatic heart disease might be present in addition to subacute bacterial endocarditis. On the 11th hospital day, the patient complained suddenly of pain in the chest. Examination revealed the pulse to be 92 and the blood pressure 170/10 mm. Hg. Broadbent's sign was present. By the next day the heart had enlarged greatly, and dyspnea was an increasingly troublesome symptom. The pericardial friction rub was louder and obscured the underlying murmurs over the entire precordium. Pulsations of the carotid and subclavian arteries became prominent. Corrigan's pulse, capillary pulsation, and pistol-shot sounds appeared. A roentgenogram of the chest revealed great increase in the enlargement of the cardiac silhouette, in addition to increasing pulmonary congestion (fig. 1). Veins in the neck were distended, and the roentgenologic studies were consistent with pericardial effusion. A pericardial tap yielded 180 cc. of bloody fluid that had a specific gravity of 1.015 and contained 3,300 leukocytes. Corticotropin, 150 mg. daily, was added to the treatment program. The next day the pericardial friction rub, though still loud, was confined to a 3 cm. area at the level of the fifth intercostal space to the left of the sternum. The fever continued. On the 14th hospital day, the blood pressure was 140/0 mm. Hg, and there was no clinical change. On the next day, four days after the sudden drop in the diastolic pressure, the patient suddenly went into peripheral vascular collapse and died. A clinical diagnosis of rupture of the aortic valve was made, and it was suspected that, *in addition to bacterial endocarditis, there might have been active* rheumatic fever.

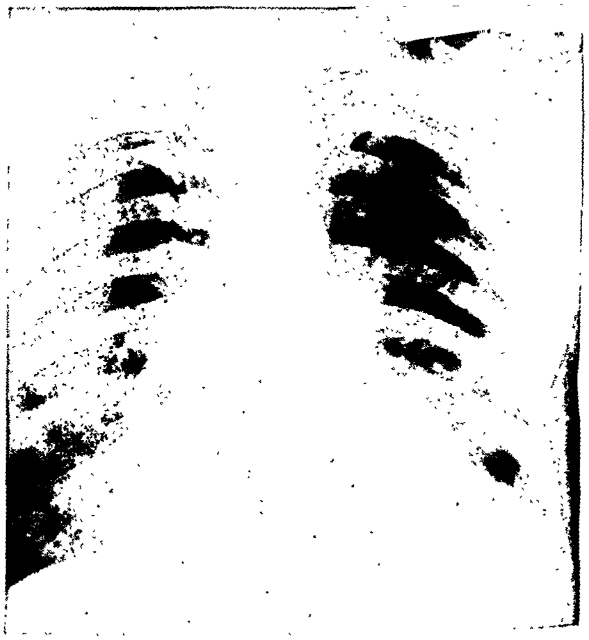

Fig. 1.—Roentgenogram of the chest on the patient's admission to University Hospitals.

Autopsy revealed the pericardial sac to be distended with approximately 2,000 cc. of grossly bloody fluid. The heart weighed 900 gm. and was covered with dense, recent, fibrinous

adhesions. The mitral valve leaflets were thickened and adherent along the margin, the valve orifice admitting only the tip of the index finger. The aortic valve cusps were irregularly thickened and partly calcified. The anterior cusp was the most seriously diseased. The ventricular surfaces of the anterior cusp and the left posterior cusp were covered with friable blood clot and debris. The body of the anterior cusp was torn with a ragged defect approximately 7 mm. in diameter. There was another perforation through the anterior and the adherent left posterior cusp that entered an opening between the sinuses of these cusps. There was a defect in the intima of the sinus of Valsalva of the anterior cusp that did not extend through the aortic wall. No gross communication could be found between the lumen of the aorta and the pericardial cavity. The left lower lobe of the lung was atelectatic. The liver and spleen were congested. The left kidney and the spleen contained several infarcts. Microscopic sections of the heart showed evidence of old rheumatic pancarditis. The vegetations of the aortic valve contained colonies of bacteria. Postmortem cultures from the heart valve yielded Pseudomonas aeruginosa and nonhemolytic streptococci.

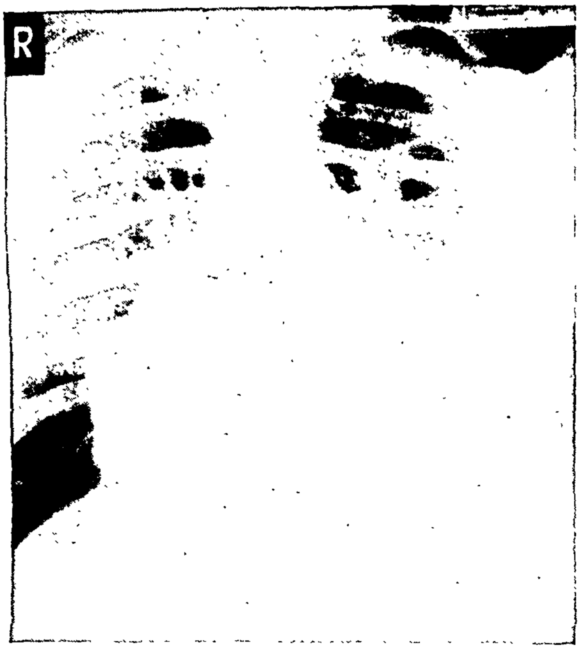

Fig. 2.—Roentgenogram of the chest one day after rupture of the aortic valve, before removal of fluid from the pericardium.

COMMENT

The diagnosis of rupture of the aortic valve in the course of subacute bacterial endocarditis has been a difficult clinical problem. The complexity is increased by the notorious variability of murmurs, which change with distortion or dilatation of the valve and the vegetation. Curious murmurs may come and go. The change of a murmur or the occurrence of a new murmur, therefore, *is not a sure sign of aortic valve rupture.* More emphasis has been given to the abrupt onset of pain in the chest. This was a prominent symptom in our patient, but its possible connection with pericarditis was hard to evaluate. Likewise, the appearance or increase of congestive failure is a helpful sign, and this was dramatic in our patient. But the most significant clinical change was the fading away of diastolic arterial pressure and the appearance of all the peripheral signs of aortic valve leak—Corrigan's pulse, capillary pulsation, and pistol-shot sounds. The sudden appearance of these signs with the advent of aortic regurgitation casts some doubt on Lewis' interpretation of such signs as a reflection of peripheral vasodilatation rather than central reflux.[3] At least the signs first appeared when the valve ruptured and the diastolic pressure vanished.

The great outpouring of bloody pericardial fluid could not be shown to have followed a dissection or rupture *through the coats of the aorta or through the heart muscle.* This possibility exists. Undoubtedly, congestive failure contributed some transudate. Anderson, Christenson, and Edwards have demonstrated hemopericardium of the myocardial infarction without rupture when "bleeding arose from pericarditis in areas removed from the infarcted myocardium."[4] Such a process may have been responsible in this case.

Is there any use in being able to discover rupture of the aortic valve during life, other than for the clinician's pride? That the diagnosis is truly difficult is indicated by the fact that only one of Carroll's 15 cases was recognized before autopsy.[2] The time may come when surgeons will be able to repair such terrible damage and save the patient.

SUMMARY

A case of rupture of the aortic valve, diagnosed before death, is reported. The abrupt decline and disappearance of the diastolic arterial blood pressure should be emphasized along with sudden pain, the advent or increase in congestive failure, and the appearance or change of an aortic diastolic murmur, as an important diagnostic sign of rupture of a diseased aortic valve in bacterial endocarditis.

DISSEMINATED LUPUS ERYTHEMATOSUS WITH INVOLVEMENT OF THE SPINAL CORD

Philip G. Piper, M.D., Madison, Wis.

A review of the literature on involvement of the central nervous system in disseminated lupus erythematosus revealed no case of focal involvement of the spinal cord in addition to the other protean manifestations. Since Hebra and Kaposi [1] and Bowen [2] described mental changes associated with this disease, Daly [3] and Sedgwick and Von Hagen [4] have more completely summarized the clinical and pathological findings. They reported toxic delirium and coma in association with the anatomic alterations of diffuse nonspecific encephalitis, as well as

vascular changes and thrombosis producing myelomalacia of the nervous parenchyma secondary to disturbances in the vascular supply. The following case is reported because of the unusual finding of vascular changes with thrombosis of the meningeal vessels resulting in ischemic necrosis of the lumbar cord.

REPORT OF A CASE

A 19-year-old white girl who had disseminated lupus erythematosus was admitted to the University Hospitals for the sixth time on May 3, 1952. She had responded fairly well to cortisone therapy until an exposure to the sun in April caused an exacerbation of the "butterfly" rash, joint pains, and fever. Immediately prior to hospitalization she experienced numbness and tingling of both lower extremities, which gradually extended up to the trunk with progressive weakness, marked diminution in motility, and difficulty with urination.

Physical Findings.—Physical examination revealed an acutely ill patient with a maculopapular erythematous rash of "butterfly" pattern over the face. Transient rhonchi were noted occasionally on the right side. The liver was palpated 2 cm. below the right costal margin, and the spleen 1 cm. below the left costal margin. The reflexes were generally hypoactive. There was considerable loss of sensitivity to pin prick in the perianal area, and a Babinski reaction was elicited on the left.

Treatment had consisted of 50 mg. of cortisone daily, which was later increased to 75 mg. to control intermittent fever. On admission the patient was given 300,000 units of crystalline procaine penicillin (Duracillin) twice daily to prevent possible infection and was given corticotropin by continuous intravenous drip. Several days later crystalline procaine penicillin and *p*-aminobenzoic acid, 3 gm. each, three times daily, were given. There was no response to therapy. The fever continued, and the patient became progressively worse. She became affected with generalized twitching and died on June 17, 1952.

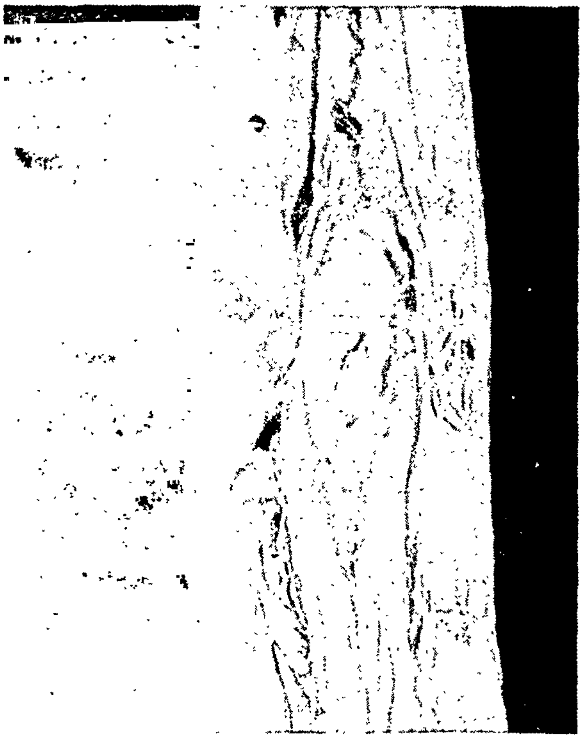

Fig. 1.—Focal swelling with infarction in the lumbar spinal cord evident on reflection of the dura.

Laboratory Data.—A positive lupus erythematosus phenomenon, albuminuria, persistent leukopenia, and normal prothrombin level were found. Serum proteins were 7.1 gm. per 100 cc., with 3.6 gm. of albumin per 100 cc. and 3.5 gm. of globulin per 100 cc. The cerebrospinal fluid protein was 175 mg. per 100 cc., blood sugar 39 mg. per 100 cc., and serum chloride 106 mEq. per liter. There were 16 white cells, most of which were lymphocytes. Result of the colloidal gold test was 5555432100, and the Wasserman reaction was negative. The Queckenstedt reaction was normal. The L. E. cells were identified by the Haserick[5] phenomenon. The mature neutrophilic leukocytes contained within the cell membrane one or more masses of nuclear material, which stained a bluish-purple color. These masses are theoretically composed of a depolymerized desoxyribose nucleic acid. The formation of the L. E. cell occurs when the blood is exposed to air outside of the body, in conjunction with the gamma globulin of the plasma of the patient. Since approximately 96% specificity can be correlated with the finding of the L. E. cell, the phenomenon in this case supported the diagnosis.

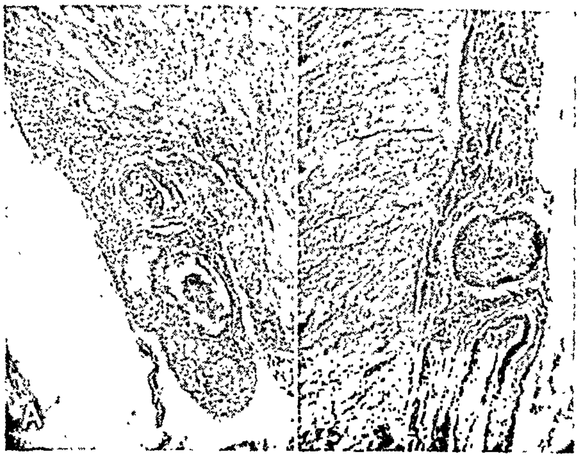

Fig. 2.—*A*, vasculitis of the meningeal vessels in the area of spinal cord swelling, with fibrinoid deposition in the vessel wall and degenerative change of the adjacent cord (× 100). *B*, a recanalized thrombus within a meningeal vessel adjacent to the area of spinal cord myelomalacia (× 100).

Autopsy Findings.—At necropsy the patient appeared older than her stated age and had a 3 + pitting edema of the lower extremities. The abdomen was distended and tympanitic. No rash was evident on the face.

When the thorax was opened, multiple fibrous adhesions were found between the visceral and parietal pleura of both chest cavities. The heart weighed 250 gm. and presented at the point of attachment of one chorda tendinea of the mitral valve a white area of discoloration, which on microscopic examination revealed a focal myocarditis filled with many inflammatory cells and scattered clusters of cocci. On culture these were identified as Staphylococcus aureus. The remainder of the heart was essentially normal. Both the right and left lungs were approximately twice normal weight. The lungs revealed areas of atelectasis, and on section a considerable amount of fluid was expressed. The cut surface revealed a confluent bronchopneumonic process involving the middle and lower right lobes and the lower left lobe.

The spleen was enlarged and weighed 500 gm. The surface presented multiple infarcts, the largest measuring approximately 3 cm. across. The pulp was firm and nonfriable, and the Malpighian corpuscles were readily identified. On microscopic examination the areas of infarction contained clusters of cocci. The liver weighed 1,750 gm. and was grossly normal as were the gallbladder, pancreas, alimentary tract, and adrenals. The kidneys each weighed 250 gm. Capsules stripped with difficulty, and the cut surfaces presented a grayish-white, mottled appearance. Small discrete foci of necrosis were identified over the surface and deep within the kidney parenchyma. Microscopic examination of these areas revealed cocci. A minimal thickening of the basement membrane of the capillaries was occasionally observed. Foci of hemorrhage were also seen. An occasional crescent was found over the glomerules in the Bowman's capsule. No "wire loop" configurations were identified within the glomerular capillaries. The ureters and bladder were normal. The pelvic organs were those of a normal woman.

---

[5] Haserick, J. R.: Plasma L. E. Test in Systemic Lupus Erythematosus, J. A. M. A. 146: 16-20 (May 5) 1951.

Examination of the brain revealed no signs of increased intracranial pressure. The pons, medulla, and cerebellum showed no gross lesions. On microscopic examination, however, the meninges were slightly thickened. The vessels were hyperemic, and certain vessels presented an acute vasculitis with perivascular demyelinization. Some of the vessels showed fibrinoid change within the wall. There were scattered petechial hemorrhages within the right basal ganglion. Examination of the spinal cord revealed a fusiform swelling in the lumbar area that measured 3 cm. in length and 1.5 cm. in diameter through the thickest portion (fig. 1). On microscopic examination through this area, the meningeal vessels presented thickening of walls, perivascular infiltration, and fibrinoid change within the walls (fig. 2*A*). All the vessels surrounding the area of enlarged cord contained thrombi, and one appeared to be recanalized (fig. 2*B*). The posterior funiculi showed myelomalacia. The anterior horns appeared intact, but there was a loss of ganglion cells in the posterior horns.

COMMENT

Since the cultures taken from the septic splenic infarcts, the kidneys, and from the area of discoloration of the chorda tendineae of the mitral valve all revealed Staphylococcus aureus, it was felt that the patient died from a fulminating staphylococcic septicemia. The lack of the characteristic findings of Libman-Sacks verrucae, "wire loop" glomerular capillaries, alteration of connective tissue of the cutis, and the fibrinoid degeneration of dispersed connective tissue of the body may well be attributed to the prolonged cortisone therapy.

Previous cases have been reported in which the essential lesion was vasculitis with fibrinoid change of the involved vessels and an associated myelomalacia and which occasionally would give rise to adhesive meningitis or chronic meningoencephalitis. It was considered that the brain lesions associated with vasculitis were incidental rather than the primary cause of death, except in those instances when gross infarction or hemorrhage occurred. Although the vessels within the brain proper and the meninges were involved, the most significant alterations in this case were in the blood supply to the spinal cord. Because of the multiple splenic infarcts, the possibility of infarction secondary to embolization of the vessels to the cord was considered; however, in this case there was no source for such an embolus. Ross and Wells[6] have reported, in a survey of the literature, that in approximately 28% of patients who died with disseminated lupus erythematosus, multiple splenic infarcts were found with no demonstrable source of emboli. The complete diagnosis was systemic staphylococcic septicemia with multiple focal septic abscesses; spinal cord swelling and degeneration due to vasculitis with thrombosis of the vessels supplying the meningeal vessels to the lumbar cord; cerebral hyperemia and minimal vasculitis; bilateral bronchopneumonia; pulmonary edema; arteriolonephrosclerosis; splenomegaly; and multiple septic splenic infarcts.

SUMMARY

A case is reported as an illustration of a rare complication of disseminated lupus erythematous, namely, vascular involvement of the spinal cord producing an infarct with resulting paralysis of the lower extremities.

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

James R. Wilson, M.D., *Secretary.*

Webster-Thomas Company, Boston.

Matchless Brand Dietetic Pack Apple Sauce.

Ingredients: Apples processed and packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Total solids 11.3%, moisture 88.7%, fat (ether extract) 0.13%, protein (N × 6.25) 0.15%, crude fiber 0.57%, available carbohydrate 9.71%, sodium 1.6 mg./100 gm.

Calories.—0.41 per gram; 11.7 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Cut Green Beans.

Ingredients: Tendergreen variety beans packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 5.2%, moisture 94.8%, fat (ether extract) 0.11%, protein (N × 6.25) 0.88%, crude fiber 0.53%, available carbohydrate 2.92%, sodium 1.02 mg./100 gm.

Calories.—0.17 per gram; 4.8 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Green Lima Beans.

Ingredients: Thorogreen variety baby lima beans packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Total solids 19.5%, moisture 80.5%, fat (ether extract) 0.28%, protein (N × 6.25) 5.80%, crude fiber 1.58%, available carbohydrate 9.51%, sodium 10.32 mg./100 gm.

Calories.—0.64 per gram; 18 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Cut Wax Beans.

Ingredients: Kinghorn variety wax beans packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 4.6%, moisture 95.4%, fat (ether extract) 0.09%, protein (N × 6.25) 0.82%, crude fiber 0.54%, available carbohydrate 2.37%, sodium 0.80 mg./100 gm.

Calories.—0.13 per gram; 3.7 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Sliced Beets.

Ingredients: Detroit dark red beets packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 8.0%, moisture 92.0%, fat (ether extract) 0.05%, protein (N × 6.25) 0.90%, crude fiber 0.53%, available carbohydrate 5.53%, sodium 46.50 mg./100 gm.

Calories.—0.26 per gram; 7.3 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Diced Carrots.

Ingredients: Red cored chantenay carrots packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 6.56%, moisture 93.44%, fat (ether extract) 0.06%, protein (N × 6.25) 0.78%, crude fiber 0.60%, available carbohydrate 4.04%, sodium 50.1 mg./100 gm.

Calories.—0.20 per gram; 5.7 per ounce.

Use.—For use in low sodium and other therapeutic diets.

X-RAYS DURING PREGNANCY

Contemporary radiobiological research has stimulated interest in and controversy over the magnitude of the radiation hazard associated with roentgen pelvimetry and other diagnostic procedures that expose the fetus to x-rays. Many aspects of the problem were discussed at a recent conference on the effects of radiation and other deleterious agents on embryonic development, sponsored by the biology division of the Oak Ridge National Laboratory, the proceedings of which will be published soon by Oak Ridge. Very little is known about the nature of whole-body radiation injury in the case of the fetus. It is probable that fetal blood-forming organs and other tissues are just as radiosensitive as adult structures and that comparable physiological disturbances occur. The present discussion is concerned only with genetic effects, particularly as they are manifested in the later development of the individual. Exposure of the fetus to sublethal doses of ionizing radiation may have two important genetic sequelae. These are gene mutations and chromosome aberrations that lead to somatic mutations and result in abnormal development of one or more of the organ systems.

The problem of the production of gene mutations is extremely complex, since they are changes in the heredity of the organism that become apparent only in the next or subsequent generations. Competent authorities differ widely in their estimates of the dose of radiation required to double the natural mutation rate per generation in man. Most of the estimates are based on studies of the fruit fly, Drosophila, and of mice extrapolated in terms of what is known about human genetics. Robley Evans' calculations suggest that doses of the order of 250 to 300 r are necessary to produce this effect. Other workers, such as Sewall Wright, H. J. Muller, D. R. Charles, and L. B. and W. L. Russell, using somewhat different assumptions, have presented estimates that are lower than Evans' by as much as a factor of 100. Nearly all the students of the subject share the belief that there is no threshold dose for gene mutation that may follow any radiation exposure however small. It should be emphasized, however, that the generally accepted level of significance for this genetic effect is a doubling of the normal or spontaneous rate of gene mutation.

Of greater practical importance is the occurrence of somatic mutations that lead to developmental defects. Since these changes are the results of chromosome injury, and since it is known that healing, or restitution, of chromosomes occurs, there should be a threshold dose for this phenomenon. This dose is not known with certainty for any species, but, in the case of one mammal, the mouse, it may be as low as 25 r. This problem has two aspects that are of clinical interest: first, the dose of radiation required and, second, the time during gestation at which it is delivered. The clinical literature contains many reports of the occurrence, and absence, of congenital malformations in children who were irradiated in utero. These reports have seemed to be contradictory and difficult of interpretation until the recent extensive animal experiments of J. G. Wilson, S. P. Hicks, and the Russells were reported. All the contemporary animal studies are consistent, and the results may be summarized conveniently by quoting from a paper of the Russells: "The developing embryo of a great variety of animal forms, including several mammals, is highly susceptible to the induction of malformations by radiation. There is no reason to doubt that this also applies to the human embryo . . . doses high enough to produce developmental abnormalities do not necessarily cause abortion or prenatal death. . . . Animal experiments have clearly demonstrated that there are well defined critical periods in the development of most characters. That is, a particular abnormality may be produced with a high incidence by irradiation at a particular stage or stages, but not at all from irradiation at other stages." [1]

The most important human material that can be compared with animal studies are less than 100 Japanese children who were exposed in utero to the detonation of the atomic bomb. Examination of these children has not revealed an abnormal incidence of skeletal abnormalities; however, the Atomic Bomb Casualty Commission has reported that, of 11 Hiroshima children who were exposed in utero to amounts of gamma radiation that approximated the median lethal dose, 7 were found to have microcephaly with mental retardation, 2 were mongolian idiots, and 2 were apparently normal. The total number of stillbirths and the number of abortions that occurred is not known with certainty, although it is reported that most pregnant women miscarried soon after the incident.

The problem of the critical time is of great interest clinically, since, to quote the Russells again: "Critical periods for the majority of gross abnormalities in mice (and also in rats) occur at a time which, in man, corresponds to the second to the sixth week of gestation. . . . Irradiation at more advanced stages in the mouse (corresponding to periods following the sixth week in man) produces less obvious and possibly more delayed effects which from the human point of view may be as harmful as the gross monstrosity." From their own studies the Russells concluded: "Whenever possible irradiation involving the uterus of women of child-bearing age should be restricted to the two weeks following the last menstrual period to preclude the possibility of fertilization having taken place. This applies particularly to diagnostic irradiation even if the doses involved are less than 25 r."

---

[1] Russell, L. B., and Russell, W. L.: Radiation Hazards to Embryo and Fetus, Radiology 58: 369 (March) 1952.

There does not appear to be any rational basis for disputing the conclusion that radiation is harmful to the fetus. The difficult problem is the statement of the amount of radiation meant when speaking of harm. From the standpoint of the geneticist who is concerned with gene mutations, any amount in excess of the natural background radiation is capable of inflicting genetic injury. The geneticist, therefore, is entirely consistent when he recommends that the fetus be protected from all radiation. Such a complete interdiction is not practical clinically, and occasions arise when it is necessary to perform roentgenologic examinations of the pelvic region because of injury, suspected dystocia, and the like. Under such circumstances an acknowledged risk is, and should be, accepted. The hazard can be minimized by the use of efficient radiographic equipment and by restricting the examination to the greatest extent compatible with obtaining the desired information. The animal experimentation provides a scientific basis for recommending that those examinations that can be deferred should be performed as late as possible in the course of pregnancy. Since the radiation exposure during fluoroscopy is usually many times greater than during radiography, fluoroscopic examinations of the pelvic region (such as of the colon or small intestine) should not be done at all during pregnancy. Since many office fluorosopes are poorly protected and seldom calibrated and are operated frequently at very high outputs it would be wise for physicians who are not qualified radiologists to defer all fluoroscopic examinations until after delivery. When the characteristics of the machine are well known and when the operator is certain that there are no x-ray leaks, cautious and brief studies of the chest and upper gastrointestinal tract should not be dangerous. The fact remains, however, that it is not possible to specify a dose of x-rays that is "safe" in the sense that it is known to be incapable of causing fetal injury.

The Russells have made an interesting suggestion to reduce the possibility of accidental radiation injury to the very young fetus. The most susceptible period in human embryogenesis appears to be between the second and sixth week of gestation, when few women are aware of the existence of pregnancy. Extensive fluoroscopic or radiographic examinations at this critical time could certainly inflict serious, unintentional injury. It is in x-ray pelvimetry and fetometry that the question of possible radiation damage has been most stressed, but, actually, from the standpoint of the number of patients involved and the doses delivered, examinations such as pyelograms, gastrointestinal examinations, and particularly the examination of the lumbosacral spine are the ones that are more apt to be dangerous. There is a sound experimental basis for the recommendation that all x-ray examinations or treatments involving the uterus should be restricted to the two weeks immediately following the end of a menstrual period. There is a good possibility that conscientious radiologists will adopt this procedure, since it involves no more than a scheduling of certain examinations. Some physicians may object to it as being excessively cautious and may even feel that their patients will become unnecessarily apprehensive about all x-ray exposures. The scientific evidence, however, demonstrates clearly that there is a basis for apprehension and that caution is justified.

MUSIC AS A THERAPEUTIC MODALITY

The use of music as a therapeutic modality is the subject of a recent communication by Arrington,[1] who declares that in acutely ill patients music often produces effects of sedation and reassurance, while in chronically ill patients music is able to divert the mind during long periods of convalescence and enforced rest. Patients with tuberculosis, rheumatic fever, malignant tumors, neurological diseases, orthopedic disorders, and many other chronic ailments frequently discover that music helps while away tedious hours and removes flights of the imagination to more pleasant and relaxing spheres of thought. This can be accomplished with the aid of background music, records, books, musical instruments, and singing.

Arrington believes that music is a useful adjunct to physical therapy. Since the active participation of patients whose limbs require remedial exercise is often invaluable, the piano, for example, provides a contraction-relaxation pattern for strengthening the upper extremities that is hardly equaled by any other musical instrument. Many patients with arm casts are able to play an instrument when the casts are properly supported. It has been observed that digital motion in patients with contractures due to burns is frequently much improved by the playing of the piano.

Since almost all children enjoy music that is tuneful, accompanied by simple words, and that relates a story, music is especially applicable as a therapeutic modality for the juvenile audience. It is useful as a vehicle accompanying games, and it also provides a pleasant distraction from the disturbing cries that invade pediatric wards of hospitals. It is of particular value to chronically ill children who are required to stay in bed for long periods of time.

According to Pichot,[2] mentally defective persons are more easily handled when soothing, rhythmic music is performed. It has been found in dentistry that music allays anxiety, raises the pain threshold, and improves the doctor-patient relationship. Many dentists play background musical recordings in their offices during annoying dental procedures; some obstetricians use music to allay anxiety and raise the pain threshold during arduous hours spent by patients in the labor room. Light [3] observed that music in the operating room served as a beneficial adjunct to the administration of local, regional, or spinal anesthesia and that it diminished apprehension in patients. A survey of a group of patients undergoing various major surgical operations indicated a very favorable response to the calming effects of music.

MEDICAL NEWS

ARKANSAS

Dr. Wells Enters Publishing Field.—Dr. Benjamin B. Wells has resigned as head of the department of medicine, University of Arkansas School of Medicine, Little Rock, to become vice-president and senior editor of W. B. Saunders Company, Philadelphia. Dr. Wells, who became associated with the school of medicine in 1942, has served as assistant professor of pathology, medical director of the University Hospital, professor of medicine, and dean of the medical school. He has been professor of experimental medicine and head of the department of medicine at the M. D. Anderson Foundation of the University of Texas Medical Center in Houston and has taught at the Baylor University College of Medicine, Houston. He received the Legion of Merit for services in the European theater during World War II. Dr. Wells is the author of "Clinical Pathology: Application and Interpretation" and "Treatment of Rheumatoid Arthritis: Current Therapy" and is coauthor with Drs. Arthur H. Sanford and J. C. Todd of "Clinical Diagnosis by Laboratory Methods."

CALIFORNIA

Orthopedic Clinic.—St. Francis Memorial Hospital, San Francisco, has opened an orthopedic clinic. Rotating their contributed time, Drs. John F. Cowan, William E. Jensen, Paul W. Klabunde, Alfred M. Palmer, and Richard J. Wagner will be on duty in the clinic, along with the resident physician, every Tuesday or Thursday, 1-2 p. m., in the physical therapy department. Resident physicians will be on orthopedic assignments for three months. The consulting staff of orthopedists consists of Drs. Delbert W. Hand, Leon O. Parker, and Horace C. Pitkin. Appointments for consultation with the resident and clinic staff physicians may be made by calling the physical therapy department (extension 384).

Personal.—Dr. James T. Weston, pathologist of the coroner's office, San Diego, has been given leave of absence for one year. Under a Damon Runyon fellowship awarded by the American Cancer Society, he will study newer methods in cancer detection at the Memorial Center for Cancer and Allied Diseases, New York.——Dr. Alvin G. Foord, director of laboratories at the Collis P. and Howard Huntington Memorial Hospital, Pasadena, for the past 22 years, has resigned but will serve as consulting pathologist.

COLORADO

State Medical Meeting in Denver.—The Colorado State Medical Society will hold its annual meeting at the Shirley-Savoy Hotel, Denver, Sept. 29-Oct. 2 under the presidency of Dr. William A. Liggett, Denver. Presentations by guest speakers include:

Alson E. Braley, Iowa City, The Ophthalmologist an Aid to Diagnosis of General Disease.
Chester B. McVay, Yankton, S. D., Inguinal and Femoral Herniplasty.
Rupert B. Turnbull Jr., Cleveland, Surgical Treatment of Ulcerative Colitis.
Frank C. Combes, New York, Cutaneous Manifestations of Systemic Disease, Part 1.
Howard F. Root, Boston, Treatment of Diabetic Coma and Its Complications.
Mr. Leo E. Brown, Chicago, Medicine's New "Platoon System."
Claude J. Hunt, Kansas City, Mo., Modern Approach to the Treatment of Thyroid Diseases.
Thomas J. Dry, Rochester, Minn., The Gallbladder and Its Relation to Coronary Disease.

Thursday at 9 a. m. a symposium on "Problems Encountered in Congenital Anomalies" will be presented by Drs. Sidney E. Blandford Jr., Robert K. Brown, and James A. Philpott Jr., Denver. Friday, 10:45 a. m., a symposium on "Surgery of Heart Diseases" will be presented by Drs. John B. Grow, Abe Ravin, and R. Parker Allen, Denver. At the annual banquet Friday, 7 p. m., an address on "Freedom of the Press and the Professions" will be delivered by Mr. Palmer Hoyt, editor and publisher of the *Denver Post.*

CONNECTICUT

Discussion on the Tuberculous Patient.—A panel discussion on "Advances in Treatment and Rehabilitation of the Tuberculous Patient Employed in Industry" will be held at Gaylord Farm Sanatorium, Wallingford, Sept. 23, at 3 p. m. A barbecue dinner will be provided at cost by the sanatorium. Interested Connecticut physicians are invited to attend this meeting, which will be sponsored jointly by the Committee on Industrial Health, Connecticut State Medical Society, and the Gaylord Farm Sanatorium.

Dr. Gray Retires from Health Department.—Dr. Albert S. Gray, Hartford, deputy commissioner of the Connecticut State Department of Health, has retired after 25 years of state service. In 1948, Dr. Gray received a citation from the Connecticut Safety Society for his work in the prevention of occupational illness in the state. He was the first chairman of the industrial hygiene section of the American Public Health Association and is a past president of the American Conference of Governmental Industrial Hygienists.

GEORGIA

County Health Board Establishes Advisory Council.—The Richmond County board of health recently appointed a special medical advisory committee consisting of the following Augusta physicians: Virgil P. Sydenstricker, Harry B. O'Rear, Walter L. Shepeard, and William S. Boyd.

Dr. Elkin to Retire from Faculty.—Dr. Daniel C. Elkin, chairman, department of surgery, Emory University School of Medicine, will retire from the faculty at the end of the 1953-1954 academic year but will maintain an advisery and consulting relationship with the school where since 1939 he has occupied the Joseph B. Whitehead chair of surgery. Dr. Elkin, a nephew of the late Dr. W. S. Elkin, dean of the Atlanta Medical College at the time it became the medical school of Emory University and first dean of the new school, served as surgeon-in-chief of the Grady Memorial Hospital in Atlanta from 1939 to 1948. He is now consultant in surgery to the Surgeon General, chief civilian consultant in surgery for the Third Army, and consultant to the Walter Reed Army Medical Center, Washington, D. C. Dr. Elkin has served as president of the American Surgical Association, the Society for Clinical Surgery, and the Southern Surgical Association, and special consultant to the U. S. Public Health Service (National Institutes of Health).

IDAHO

Society News.—The Southwest Idaho District Medical Society has elected Dr. Lowell B. Privett, Boise, president; Dr. Lester L. Shupe, Caldwell, vice-president; Dr. Max F. Bell, Boise, secretary; and Dr. A. Curtis Jones, Boise, treasurer.——At the annual meeting of the Idaho Chapter of the American College of Surgeons in Boise Dr. Arthur V. Jones Sr., Boise, was elected president, Dr. Albert B. Pappenhagen, Orofino, vice-president, Dr. James H. Hawley, Boise, secretary, and Dr. Charles B. Beymer, Twin Falls, counselor.

ILLINOIS

Conference on Exceptional Children.—The Illinois Commission for Handicapped Children will sponsor the 10th Governor's Conference on Exceptional Children Sept. 25 at the Palmer House, Chicago. Group meetings will be arranged for the handicapped child in preschool, in the regular school

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

program, in the community recreation program, and in institutions. During a symposium on "Generic Casework and the Handicapped Child," Dr. M. Jeanne Spurlock, psychiatrist, Institute for Juvenile Research, Chicago, will discuss "Attitudes of Caseworkers That Help or Hinder." Featured speaker for the conference luncheon will be the Rev. Harold Wilke, pastor of St. Paul's Evangelical and Reformed Church, Crystal Lake, Ill., former chaplain in military hospitals, and for several years a faculty member of the Menninger Foundation school of psychiatry in Topeka, Kan. "A Reporter's Round-Up of the Conference" will be presented by Mr. Eugene J. Taylor, staff writer, *New York Times*, and co-author with Dr. Howard A. Rusk, New York, of "New Hope for the Handicapped."

Chicago

Society News.—The north side branch of the Chicago Medical Society will meet at 8 p. m., Oct. 1, in the ballroom of the Drake Hotel, Lake Shore Drive and Upper Michigan Ave. Dr. Hiram T. Langston, Riverside, Ill., will speak on "Carcinoma of the Lung."

Personal.—Dr. Ben W. Lichtenstein presented a paper on "Sturge-Weber-Dimitri Syndrome Cephalic Form of Neurocutaneous Hemangiomatosis" at the International Neurological Congress in Lisbon, Portugal. Dr. Percival Bailey, who also attended that congress and the German Neurological Congress at Munich, has been invited to address a meeting at Seville, Spain, on "Psychomotor Epilepsy," and Dr. Paul C. Bucy will present "Experimental Studies on the Temporal Lobe." All are professors at the University of Illinois College of Medicine.

IOWA

Dr. Heeren Named Deputy Health Commissioner.—Dr. Ralph H. Heeren, Des Moines, has been named Iowa state deputy commissioner of health. He formerly served as associate professor of preventive medicine, State University of Iowa College of Medicine, Iowa City. Affiliated with the Iowa state department of health since 1948, he was previously director of the division of communicable diseases, state health department of Oklahoma. He has served on the faculties of Western Reserve University School of Medicine, Cleveland, and Tulane University of Louisiana School of Medicine, New Orleans; has been affiliated with Mt. Sinai Hospital, Cleveland, and Albany (N. Y.) Hospital; and was a Rockefeller Foundation fellow in the school of public health at Harvard Medical School, Boston.

Personal.—Dr. Paul D. Anneberg, Carroll, has been made president of the Rotary Club.——Dr. J. Frank Aldrich, Clarinda, who recently retired from active medical practice after 55 years, was honored during an open house program at Hand Memorial Hospital in Shenandoah. During the ceremonies Dr. Aldrich presented the hospital board with a check for $1,000 in memory of his wife.——In recognition of his 50 years of practice Dr. Henry D. Jones was guest of honor at a meeting of the Schleswig business men's club, which presented him with a testimonial scroll. The scroll listed his many services to the community, including "hardships of his early practice, during the horse and buggy days, and before the era of good roads; willingness during his professional career to answer every call, without thought of personal comfort or financial remuneration; and genuine interest in community welfare."——Dr. Edmund G. Zimmerer, Des Moines, former director of the Division of Cancer Control, Iowa State Health Department, and member of the National Cancer Institute Cancer Control Committee, has been appointed Iowa State commissioner of health for a four year term.——Dr. Louis H. Kornder, Davenport, is retiring after 35 years of practice and will devote himself to civic interests. Dr. Kornder is president of the board of the Davenport museum, vice-president of the Municipal Art Gallery, curator of the Iowa State Historical Society, and a trustee of Dubuque University.——Dr. Eugene Tinsman, who has practiced in Orient for 50 years, was recently honored by an open house in the school building. Dr. Tinsman has served 12 years on the Orient school board.

KANSAS

Cancer Diagnostic Clinic at Chanute.—Neosho Memorial Hospital, Chanute, recently organized a cancer diagnostic clinic, after having established a cancer registry and follow-up service a year ago. Cancer control activities in Kansas are jointly sponsored by the Kansas Medical Society's committee on cancer control, the Kansas Division of the American Cancer Society, and the cancer section of the Kansas State Board of Health.

KENTUCKY

State Medical Meeting in Louisville.—The annual meeting of the Kentucky State Medical Association will convene at the Columbia Auditorium, Louisville, Sept. 22-24. The general session, which is designated as the Lewis Rogers Memorial meeting, will be called to order by the president, Dr. Guthrie Y. Graves, Bowling Green, at 9 a. m. Tuesday. At the president's luncheon, Roof Garden, Brown Hotel, at noon, Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, will speak on "Firm Ground for Medicine." Other guest speakers include:

George T. Harrell, Winston-Salem, N. C., How Antibiotics Work.
Robert M. Zollinger, Columbus, Ohio, Indications for Surgery in the Jaundiced Patient.
Orville B. Coomer, D.D.S., Louisville, Growing Interdependence of Medicine and Dentistry.
Harold E. Harris, Cleveland, Indications and Contraindications of Tonsillectomy.
Paul H. Holinger, Chicago, Bronchial Obstruction: Its Significance in Pulmonary Disease.
Mr. Leo E. Brown, Chicago, PR Profits.
Col. William H. Amspacher, Fort Sam Houston, Texas, Early Care of the Severe Burn.
Donald A. Covalt, New York, Rehabilitation of the Hemiplegic Patient.
Mr. C. Joseph Stetler, Chicago, The Legislative Program and Activities of the A. M. A.
H. Close Hesseltine, Chicago, Changing Patterns in Obstetric Practice.

The presidential address will be delivered Wednesday, 10 a. m., and the oration in medicine, "Heart Disease From the Patient's Viewpoint," will be given at 11:30 a. m. by Dr. Paul W. Simpson, Covington. The annual banquet will be held Thursday 7:30 p. m. in the Crystal Ballroom of the Brown Hotel (dress optional). Mr. Allan Kline, president, American Farm Bureau, will speak on "Promises and Prospects." The woman's auxiliary will meet concurrently at the Brown Hotel where, on Wednesday, Dr. Graves and Dr. J. Duffy Hancock, Louisville, president-elect of the Kentucky State Medical Association, will participate in the panel on public relations.

MICHIGAN

Meeting of Medical Assistants.—The fourth annual convention of the Michigan State Medical Assistants Society will be held at the Pantlind Hotel, Grand Rapids, Sept. 23-24. On Wednesday Dr. Luther C. Carpenter Jr., Grand Rapids, will speak on "Cancer," and Dr. David G. Dickinson, Ann Arbor, will discuss "Poliomyelitis." Luncheon at 12:30 p. m. will follow a presentation on "Legal Aspects in Medicine" by William A. Perkins, LL.B., Grand Rapids. At the banquet, 7:30 p. m., A. E. Schneider, Ph.D., Kalamazoo, will have as his topic "Your Attitude and You." Thursday morning Dr. Edwin O. Pearson, Kalamazoo, will discuss "X-Ray and X-Ray Therapy," and Dr. Anthony F. Stiller, Oshtemo, will talk on "Tuberculosis." The president's luncheon, 12:30 p. m., will be followed by a presentation on "History of Medicine" by Harvey M. Merker, D.Sc., consultant to Parke, Davis & Company, Detroit.

State Medical Meeting in Grand Rapids.—The Michigan State Medical Society will hold its annual session at the Pantlind Hotel, Grand Rapids, Sept. 23-25 under the presidency of Dr. Reader J. Hubbell, Kalamazoo. Discussion conferences will be conducted each day from 12 to 1 p. m. There will be a public meeting Wednesday, 8:30 p. m., in the Civic Auditorium, where many of the scientific sessions will convene. After the presidential address and induction of members into the 50 year club, Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, will speak on

"Organized Medicine—Its Progress and Problems." At 9:15 p. m. the Andrew P. Biddle lecture on "World Affairs and Foreign Policy" will be delivered by U. S. Senator Homer Ferguson, Detroit. On Thursday, which has been designated as general practice day, the following program will be presented by out-of-state speakers:

Chevalier L. Jackson, Philadelphia, What Can Bronchoscopy Do for the General Practitioner?
Michael L. Mason, Chicago, The Crushed Hand.
George E. Shambaugh Jr., Chicago, Management of Hearing Impairments.
Blair Holcomb, Portland, Ore., Patients Are People—A Physician's Soliloquy.
Allan C. Barnes, Cleveland, Management of the Infertile Couple.
Arthur T. Hertig, Boston, Genesis of Uterine Cancer, Cervical and Endometrial.
Victor A. Najjar, Baltimore, Jaundice in Infancy and Childhood.
Louis A. M. Krause, Baltimore, Physical Examination.

The following presentations will be made by other out-of-state speakers during the sessions:

Walter G. Maddock, Chicago, Development and Management of Gastrointestinal Distention.
William D. Holden, Cleveland, Place of Radioactive Isotopes in Clinical Practice.
Everett I. Evans, Richmond, Va., Treatment of the Severely Burned.
Frank Hinman Jr., San Francisco, Clinical Use of Testosterone.
Leo M. Taran, Roslyn, L. I., N. Y., Management of Rheumatic Fever and Rheumatic Heart Disease.
William L. Benedict, Rochester, Minn., Multiple Sclerosis.
David P. Findley, Omaha, The Postcesarean Baby.
O. Spurgeon English, Philadelphia, Treatment of Psychosomatic Illness.
Jacob A. Bargen, Rochester, Minn., Problems of Nutrition in Ulcerative Disease of the Digestive Tract (Beaumont lecture).
John G. Downing, Boston, Oral and Cutaneous Clues in Medicine and Surgery.
Leo G. Rigler, Minneapolis, Hepatography—The Roentgen Examination of the Liver.
John W. Knutson, D.D.S., Washington, D. C., An Evaluation of the Grand Rapids Water Fluoridation Supply.
Paul R. Cannon, Chicago, Successes and Failures in Relation to the Problem of Parenteral Alimentation.
Harold J. Magnuson, Chapel Hill, N. C., Interpretation of Positive Serologic Tests for Syphilis in Clinically Negative Patients.
Norman M. Keith, Rochester, Minn., Factors in Treatment of Edema.
Leslie N. Gay, Baltimore, The Dramatic Story of Dramamine.
Julian Johnson, Philadelphia, Present Status of the Surgery of Mitral and Aortic Stenosis.

MINNESOTA

Dr. Melby Night.—Dr. Benedik Melby, Blooming Prairie, was honored by the community on "Dr. Melby Night," when he was presented with a gold clock and pen desk set and a framed, hand-lettered scroll commemorating his 50th anniversary in the practice of medicine. Dr. Melby has been a member of the board of education for 39 years. In February, 1951, he was awarded a scroll by the Minnesota Educational Association for his interest and work in the public schools.

NEW YORK

Lecture on Psychosomatic Gynecology.—Dr. William S. Kroger, Chicago, will speak on "Psychosomatic Gynecology," Sept. 24, 8:30 p. m. in the Jewish Sanitarium and Hospital for Chronic Diseases, 86 E. 49th St., Brooklyn. The lecture is presented by the gynecologic service.

Personal.—After 14 years of service at the Ray Brook State Tuberculosis Hospital in Ray Brook, Dr. Joseph Gordon, principal thoracic surgeon, has resigned and has entered the private practice of thoracic surgery at 106 S. Girard St., Albuquerque, N. Mex.

NORTH CAROLINA

University News.—Dr. David Cayer, who has been associate professor of internal medicine, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, since July 1, 1949, has been promoted to professor of gastroenterology.

Personal.—Dr. W. Nelson Thompson, Raleigh, has been appointed medical director of the Durham Life Insurance Company.——Dr. Coy C. Carpenter, dean of the Bowman Gray School of Medicine, Winston-Salem, has been awarded a Fulbright visiting professorship in pathology for a nine month lecture series in Cairo, Egypt.——Joseph E. Markee, Ph.D., professor of anatomy, Duke University School of Medicine, Durham, has been chosen as the fourth honorary member named by the American Orthopedic Association since its founding in 1887. The society honored Dr. Markee for his work in audiovisual education, particularly development of teaching aids in orthopedic surgery. Dr. Markee was made an honorary member of the American Academy of Orthopedic Surgery in 1950.——Dr. Wingate M. Johnson, Winston-Salem, served as moderator for a panel on "Aging" at the annual meeting of the North Carolina Public Health Association in Nags Head, Sept. 10-12.

PENNSYLVANIA

Anesthesiologists Meet in Pittsburgh.—The annual meeting of the Pennsylvania Society of Anesthesiologists will be held in Pittsburgh Sept. 25-26. Out-of-state speakers include:

C. Paul Boyan, New York, Ganglionic Blockade During Anesthesia.
Emery A. Rovenstine, New York, Cyclopropane.
Anthony J. Bayuk, Youngstown, Ohio, Use of Orthoxine in Anesthesia.
Maurice S. Segal, Boston, Advances in Inhalation Therapy.

Personal.—For his entry "Physicians and Medicine on Stamps," Dr. Herbert B. Shearer, Worcester, received the grand award at the International Stamp Exhibition held at the National Philatelic Museum, Philadelphia, under the auspices of the American Topical Association. Dr. Shearer's collection of "U. S. Christmas Seals and Red Cross Stamps of the World" won first prize in the section of "International Organizations." ——Dr. Herman W. Rannels, chief of obstetrics and gynecology, St. Joseph's Hospital, Lancaster, has become one of the directors of the Hunterdon Medical Center in Flemington, N. J. The directorship includes a teaching position on the staff of New York University-Bellevue Medical Center, with which the center is affiliated.

Philadelphia

Phi Delta Epsilon Lecture.—Beta Zeta chapter, Phi Delta Epsilon fraternity, Hahnemann Medical College and Hospital of Philadelphia, has announced its annual lectureship to the medical profession, Oct. 2, 8 p. m. at Klahr Auditorium, 235 N. 15th St. Dr. Nicholson J. Eastman, Baltimore, will speak on "25 Years of Obstetric Pain Relief: What Have We Learned?"

Mental Health Director Wanted.—The Philadelphia Department of Public Health has an opening for a director of its new division of mental health. Applicants are required to have seven years of clinical psychiatric experience, including three years in charge of other psychiatrists, one year in children's psychiatry, and three years in approved training centers, that have led to certification by the American Board of Psychiatry and Neurology. The starting salary is $13,442. Closing date for applications is midnight, Oct. 21.

TEXAS

General Practitioners Meet in Dallas.—The annual scientific assembly of the Texas Academy of General Practice will be held at the State Fair Auditorium in Dallas, Sept. 21-23. Out-of-state guest speakers include:

Francis L. Chamberlain, San Francisco, Specific Treatment of Hypertension. Recent Advances in Electrocardiography of Importance in General Practice.
Henry H. Turner, Oklahoma City, Endocrine Disorders of Childhood. Psychosomatics and Pseudoendocrinopathies.
Edgar Hull, New Orleans, Hints in Recognition of Certain Endocrine Diseases. Asymptomatic Organic Disease.
Henry W. Brosin, Pittsburgh, Interviewing Techniques. Depressive Reactions in General Practice.
Somers H. Sturgis, Boston, Problems of Sterility. Diagnosis and Treatment of Amenorrhea.
Benjamin J. Wolpaw, Cleveland, Retinal Changes in Hypertensive Vascular Disease. External Diseases of the Eye as Seen by the General Practitioner.
Marcus J. Stewart, Memphis, Diagnosis and Treatment of Minor Foot Problems. Differential Diagnosis of Low Back Pain.
Alton Ochsner, New Orleans, Diagnosis of Cancer of the Lung. Diagnosis and Treatment of the Post-Phlebitic Extremity.
Philip Thorek, Chicago, Appendicitis. Diagnosis and Treatment of Breast Lesions.
Henry M. Weyrauch Jr., San Francisco, Pitfalls in Urologic Diagnosis. Office Treatment of Common Urologic Conditions.

The fee is $20. Nonmembers are invited to attend. Entertainment for the physicians' wives has been arranged.

Industrial Health Conference in Houston.—The Houston Chamber of Commerce will sponsor the sixth annual Gulf Coast Conference on Industrial Health at the Shamrock Hotel, Houston, Oct. 1-3. During the symposium on "Employment of the Cardiac" Thursday afternoon, Dr. Harold M. Marvin, New Haven, Conn., will discuss "The Physician's Dilemma," and Dr. Kenneth E. Markuson, Helena, Mont., will speak on "The Insurance Carrier Views the Problem." Vice Admiral Ross T. McIntire (MC), U. S. N., Ret., Washington, D. C., will speak. Dr. Robert L. King, Seattle, will serve as moderator for a panel discussion at 4:30 p. m. during which previous speakers will participate in a question and answer period. Other physicians participating in the Thursday program include Dr. Theodore M. Frank, Texas City, who will serve as co-chairman of the morning session; Dr. Paul V. Ledbetter, Houston, co-chairman of the luncheon session; Drs. Sidney Schnur and Valliant C. Baird, Houston, chairman and co-chairman, respectively, of the afternoon session. The morning session will be presented by Dr. George M. Saunders, New York ("The Executives' Health Problem"), Dr. Charles H. Hine, Berkeley, Calif. ("Methods of Establishing Safe Handling Procedures for Compounds Developed by the Petro-Chemical Industry"), and Dr. Robert E. Eckardt, Linden, N. J. ("A Medical Research Program in Industry"). Speakers for the luncheon sessions are Dr. Robert L. King, Seattle, who will report on the American Heart Association, of which he is president, and Dr. Marvin, New Haven, Conn., who will discuss "The Executive and His Heart." At the evening session in the Prudential Building Auditorium, Vice Admiral McIntire will present "Recovery of Human Resources Through Rehabilitation." Friday morning will be devoted to a symposium on "The Noise Problem in Industry":

C. Richard Walmer, Pittsburgh, Noise in Industry—The General Problem.
James H. Sterner, Rochester, N. Y., Industrial Noise—Its Medical Aspect.
Rear Admiral Herbert Lamont Pugh, Washington, D. C., Noise, Noxious or Nice.
Jack L. Bangs, Ph.D., Houston, Testing for Hearing Loss and Its Application to Industry.

Friday afternoon Dr. Arthur J. Vorwald, Saranac Lake, N. Y., will present "Medical Aspects of Air Pollution" in a symposium on "Waste Disposal Problems," which will be preceded by a film showing on "The City That Disappears."

GENERAL

United Cerebral Palsy Appoints Chairman.—Dr. H. Houston Merritt, director of the Neurological Institute of the Columbia-Presbyterian Medical Center, New York, has been appointed chairman of the board, which coordinates the work of the organization's five volunteer medical and professional boards and sets over-all policy. Dr. Merritt succeeds Dr. Sidney Farber, professor of pathology at Harvard Medical School, Boston, who will continue to serve as chairman of the Research Advisory Board. Taking over as chairman of the Clinical Advisory Board, a position formerly held by Dr. Merritt, is Dr. Charles F. McKhann, professor of pediatrics at Jefferson Medical College, Philadelphia.

Cancer Society Fellowships.—The American Cancer Society has announced that its program of clinical fellowships will continue through the next institutional training year to June 30, 1955. The program for the coming year will include support for clinical traineeships. These traineeships, which are opportunities for training for physicians at a level somewhat lower than the clinical fellowship, carry stipends up to a maximum of $3,600. Fellowships and traineeships will be made available primarily to teaching institutions approved by the Council on Medical Education and Hospitals of the American Medical Association. Applications should be addressed to Dr. Brewster S. Miller, American Cancer Society, 47 Beaver St., New York 4. The deadline for filing applications is Oct. 5. Application forms are not necessary.

Medical Illustrators Meet in Baltimore.—The annual convention of the Association of Medical Illustrators will be held at the Johns Hopkins Medical Institutions, Baltimore, Oct. 5-7. Participating in the program will be Drs. Alan C. Woods, Baltimore ("The Value of Art in Ophthalmology as Opposed to Photography"), Victor A. McKusick, Baltimore ("The Hutchinson Collection"), and David S. Ruhe, Chicago ("Role of the Illustrator in a Changing Medical Audiovisual Program in the Medical Center"). Dr. Jonas S. Friedenwald, Baltimore, associate professor of ophthalmology at Johns Hopkins Medical School since 1931, will deliver the Brödel Memorial lecture on "Advances in Visual Physiology and the Portrayal of Depth of Space in Painting" after the dinner meeting on Tuesday. Monday at 8 p. m. there will be a tour of the new photographic department, Johns Hopkins Hospital Reconstruction Unit #1. At 8:45 p. m. movies will be shown on "Embryology of the Eye," "Amebic Dysentery," and "Carcinoma of the Prostate."

Meeting of Neurosurgical Society.—The Neurosurgical Society of America will hold its annual meeting at the Broadmoor Hotel in Colorado Springs, Colo., Sept. 23-26 under the presidency of Dr. William F. Meacham, Nashville, Tenn. Thursday morning will be devoted to a "Forum on Clinical Problems as Related to Diagnosis," for which the moderators will be Drs. Francis J. Otenasek, Baltimore, Theodore B. Rasmussen, Chicago, and Christian Keedy, Miami, Fla. Dr. Kenneth E. Livingston, Portland, Ore., will serve as chairman for the Thursday afternoon symposium on "Present Status of Psychosurgery Including the Legal Aspects." Participants will be Drs. C. Douglas Hawkes, Memphis, Tenn., Alfred Uihlein, Rochester, Minn., Arthur A. Morris, Washington, D. C., and John R. Green, Phoenix, Ariz. There will be a panel Friday morning on "Metabolic and Electrolytic Problems in Neurosurgery," in which Drs. Eben Alexander Jr., Winston-Salem, N. C., Irving Cooper, New York, Jean M. Hawkes, Memphis, Tenn., and Robert M. Salassa, Rochester, Minn., will participate. The golf tournament will be on Friday afternoon. The banquet (formal), 7:30 p. m., will be preceded by a cocktail hour. Speaking by invitation Saturday morning will be Drs. Arthur A. Morris and Clemmer M. Peck, Washington, D. C. ("Anatomy of Anterior Cerebral Artery as Demonstrated by Arteriography") and Drs. Lester A. Mount and Juan M. Taveras, New York ("Study of Collateral Circulation of the Brain Following Various Ligations Intracranially and in the Neck"). At 6 p. m. Saturday there will be a steak fry in the canyon.

Pediatricians Meet in Miami.—The American Academy of Pediatrics will hold its annual meeting in the Municipal Auditorium, Miami, Fla., Oct. 6-9 under the presidency of Dr. Philip S. Barba, Philadelphia. Two day instruction courses (enrollment limited to from 35 to 50 in each seminar) will be presented Oct. 4-5. Fee for each seminar is $30. The following presentations will be made:

Lawson Wilkins, Baltimore, Pediatric Endocrinology.
Helen B. Taussig, Baltimore, Heart Disease in Children.
Randolph K. Byers, Boston, Pediatric Neurology.
Richard E. Wolf, Cincinnati, Pediatric Psychiatry.
Julius B. Richmond, Chicago, Pediatric Psychiatry.
Susan C. Dees, Durham, N. C., Pediatric Allergy.
Weston M. Kelsey, Winston-Salem, N. C., Electrolyte and Mineral Balance.
Harry H. Gordon, Baltimore, Problems in the Management of the Premature and Newborn Infant.
J. Cyril Peterson, Nashville, Tenn., Pediatric Hematology.

Round-table discussions (half day courses with limited enrollment for from 35 to 50) will be run concurrently with the general sessions Oct. 6-8. Fee for each discussion is $5. During the general sessions there will be symposiums on "Health Evaluation of the Normal Child" (chairman, Dr. Thomas E. Shaffer, Columbus, Ohio); "Physiology of the Gastrointestinal Tract and Its Functional Disturbances" (chairman, Dr. L. Emmett Holt Jr., New York); "Respiratory Problems Affecting the Premature and Full-Term Infant" (chairman, Dr. Stewart H. Clifford, Boston); and "Respiratory Viral Diseases" (chairman, Dr. Joseph Stokes Jr., Philadelphia). Dr. Sidney Farber, Boston, will conduct clinical pathological conferences Monday, 2-5 p. m. and with Dr. Waldo E. Nelson, Philadelphia, Friday, 11:20 a. m. Thursday morning the Borden award paper will be read by Dr. Lawson Wilkins, Baltimore; the first Mead Johnson award paper by Drs. Frederick C. Robbins and Thomas H. Weller, Boston; and the second Mead Johnson award paper by Dr. Margaret H. Smith, New Orleans. The annual banquet will be held Thursday evening.

Southwestern Surgical Congress.—This congress will hold its annual meeting at the Hotel Utah, Salt Lake City, Sept. 21-23 under the presidency of Dr. Louis P. Good, Texarkana, Ark. Morning sessions will open at 8 a. m. with the showing of motion pictures. Monday, 11 a. m., Dr. Warren H. Cole, Chicago, will present "Management of Strictures of the Common Duct." At 9:50 a. m. Drs. James Barrett Brown, St. Louis, and Minot P. Fryer, St. Louis, will speak on "Management of Hemangioma and Nevi." At 2 p. m. Dr. William H. Moretz, Salt Lake City, will serve as moderator for a panel on trauma, with the following participants, all of Salt Lake City: Drs. Woodrow Nelson, Chester B. Powell, Paul A. Pemberton, Preston R. Cutler, and Robert R. Robinson Jr. At 3:30 p. m. the sessions will adjourn for a trip to Brighton Resort. Tuesday, 9:20 a. m., Dr. Henry Plenk, Salt Lake City, will speak by invitation on "Gastric Ulcers—A Correlative Study," after which Dr. Samuel F. Marshall, Boston, will discuss "The Problem of Jejunal Ulcer." At 11 a. m. Dr. Everett D. Sugarbaker, Jefferson City, Mo., will present "Internal Mammary Node Removal in Continuity with Radical Mastectomy." At 2 p. m. Dr. Marshall will be guest moderator for a panel on "Management of Goitre," in which Drs. Lawrence P. Engel, Kansas City, Mo., Geno Saccomanno, Grand Junction, Colo., and John Z. Bowers, Salt Lake City, will serve as participants. At 3 p. m. Dr. Goode will deliver the presidential address, "The Methods and Manners of Great Men of Medicine." Cocktails, 6:30-7:45 p. m., at the Alta Club will precede the dinner dance. Wednesday, 9:40 a. m., Dr. Philip B. Price, Salt Lake City, will speak on "An Experimental Study of Burn Wounds." At 11 a. m. Dr. Marshall will discuss "Surgical Management of Regional Enteritis and Its Complications." At 2 p. m. there will be a panel on "Diseases of the Colon and Rectum" with Dr. Thomas G. Orr, Kansas City, Kan., as moderator, and Drs. Edgar J. Poth, Galveston, Texas, Kenneth C. Sawyer, Denver, and Leo J. Starry, Oklahoma City, as participants. Luncheon and roundtable discussions will be held daily, 12:30-2 p. m.

College of Surgeons Meeting in Chicago.—The annual clinical congress of the American College of Surgeons will be held at the Conrad Hilton, Chicago, Oct. 3-9. Dr. Harold L. Foss, Danville, Pa., president, will preside at the opening evening session, at which Dr. Fred W. Rankin, Lexington, Ky., will be installed as president for 1954. Subjects for panel discussion include "Management of Gastric Ulcers," "Carcinoma of the Mouth," "Blood Transfusions: Complications and Their Management," "Polyposis of the Colon," "Surgery of the Spleen," and "Malignant Thyroid Disease." Panel discussions in the surgical specialties will be held Friday afternoon. On Tuesday, 2-5 p. m., there will be a symposium on trauma at the Eighth Street Theatre. Wednesday, 2-5 p. m., a symposium on cancer will be held at the John B. Murphy Memorial Auditorium. Thursday, 1:30-3 p. m., a symposium on graduate training in surgery and the surgical specialties is scheduled for the Conrad Hilton. A motion picture symposium on unusual conditions encountered in abdominal surgery will be held Thursday, 8-10 p. m. Clinical pathological conferences are scheduled for 1:30 p. m. Monday and Wednesday. Surgical procedures at Albert Merritt Billings Hospital will be color televised to the hotel every day under the sponsorship of Smith, Kline and French Laboratories of Philadelphia. Twelve forums on fundamental surgical problems will present the latest research findings. At an evening session Monday, Dr. Foss will deliver the presidential address. The eighth Martin Memorial lecture will be delivered by Sir James Paterson Ross, vice-president, Royal College of Surgeons of England, who will discuss "Science and Surgery." During the Wednesday evening session Dr. J. William Hinton, New York, will speak on "Cardiac Arrest: Etiology and Management from a Study of Over 1,300 Cases," and Dr. Francis D. Moore, Boston, will discuss "Metabolic and Electrolyte Abnormalities in Severely Ill Cardiac Patients and Individuals with Advanced Cancer." "Present Day Problem of Nonpenetrating Abdominal Trauma" is the subject of the Oration on Trauma to be delivered by Dr. William L. Estes Jr., Bethlehem, Pa. The Friday evening session at Medinah Temple will close with an address on "The Responsibility of a Heritage of Idealism" by Dr. Fred W. Rankin. Registration fee for nonfellows and fellows whose dues are not paid to Dec. 31, 1952, will be $20. Registration forms may be obtained from the American College of Surgeons, 40 E. Erie St., Chicago 11.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

PHILIPPINE ISLANDS

Pilot Project in Bilharziasis Control.—Plans have been drawn for construction of a technical center on the Island of Leyte to serve as the headquarters for a six year pilot project in bilharziasis control. This building will house research laboratories and administrative offices, as well as an aquarium for the study of snails, vectors of bilharziasis. It is estimated that 40 persons will be employed at the center. A three man international team to be provided by WHO for this project will work with a matching team of experts from the Department of Health of the Philippines. The aim of the pilot project will be to determine the best method of controlling bilharziasis, which is believed to afflict hundreds of thousands of persons in the Philippines. The length of the project is necessitated by the fact that there is insufficient knowledge concerning practicable and economical means in the control of this disease.

CANADA

National Immunization Week.—National Immunization Week will be observed from Sept. 27 to Oct. 3, under the leadership of the Health League of Canada. This is a nationwide educational campaign to bring to the attention of all parents the protection against diphtheria, whooping cough, lockjaw, and smallpox that is available for their children. Dr. Franklyn O. Wishart, professor of hygiene and preventive medicine, University of Toronto, is chairman of the Health League's National Immunization Committee.

FOREIGN

Aero Medical Meeting.—The interim meeting of the Aero Medical Association will be held under the auspices of the French Speaking Branch at the University of Brussels Medical School, Brussels, Belgium, Sept. 24-27. Rear Admiral Bertrand Groesbeck Jr. (MC) USN (Ret.), Washington, D. C., is president of the association, and Major General Charles Sillevaerts, former chief of the Belgian Air Force Medical Service, is president of the French speaking group. A symposium on jet pilot fatigue will be held Thursday. Other topics to be discussed include: "Modifications of Arterial Pressure of Men During Breathing in Overpressure," "Threshold of Organic Disturbances During Inhalation of Pure Oxygen," "Some Changes of Performances with Age and Their Reference to Aircrew," "Medical Aspects of Abnormal Use of Ejectable Seats," "Research on Human Factor in Accidents," "Is Electrophrenic Respiration of Any Use in the Reanimation of Subjects in Anoxemic Fainting State?" and "Research on the Pharmaco-Dynamic Factors Which Can Modify Endurance to Anoxia."

DEATHS IN OTHER COUNTRIES

Dr. Erasto Gaertner, mayor of the city of Curitiba, State of Parana, Brazil, died May 19, 1953. Dr. Gaertner was professor of the surgical clinic, ex-professor cathedrat of obstetrics, and professor of the urologic clinic of the faculty of the University of Parana. He was founder and director of the Institute of Medicine and Surgery of Parana, as well as founder of the clinic of tumors of the Institute of Medicine and Surgery of Parana. He served as deputy and constituent of the State Assembly of Parana in 1935, as deputy constituent of the National Assembly in 1946, and he was a member of the committee on education and culture of the Deputy Chambers.

CORRECTION

Carbon Dioxide Inhalation in Muscular Rigidity.—In the article on this subject in The Journal, Aug. 22, the word alkylosis in the second paragraph on page 1624 under the heading "Background" should be alkalosis.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec. 1-4.
1954 Annual Meeting, San Francisco, June 21-25.
1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Meeting, Atlantic City, N. J., June 6-10.
1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Sept. 30-Oct. 2. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago 10, Director.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct. 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Municipal Auditorium, Miami, Fla., Oct. 6-9. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Association of Medical Clinics, Congress Hotel, Chicago, Oct. 9-11. Dr. Edwin P. Jordan, P. O. Box 114, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, Palace Hotel, San Francisco, Oct. 5-9. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Secretary.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 1-3. Dr. James K. Stack, 700 North Michigan Blvd., Chicago, Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American College of Surgeons, Conrad Hilton Hotel, Chicago, Oct. 5-9. Dr. Michael L. Mason, 40 East Erie St., Chicago, Secretary.

American Dental Association, Cleveland, Sept. 28-Oct. 1. Dr. Harold Hillenbrand, 222 E. Superior St., Chicago 11, General Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15 Dr. H. W. Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Medical Writers' Association, Elk's Club, Springfield, Ill., Sept. 23. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Netherland Plaza, Cincinnati, Sept. 29-Oct. 2. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Olympic Hotel, Seattle, Oct. 6-9. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Sheraton Hotel, Baltimore, Oct. 5-7. Miss Evelyn J. Erickson, 1512 St. Antoine St., Detroit 26, Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association of State and Territorial Health Officers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 29-Oct. 2. Mr. Harvey T. Stethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Constantinian Society, Battery Park Hotel, Asheville, N. C., Oct. 18-21. Dr. C. F. Shook, Medical Director, Owens-Illinois Glass Company, Toledo 1, Ohio, Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14. Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington 6, Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Gulf Coast Conference on Industrial Health, Shamrock Hotel, Houston, Tex., Oct. 1-3. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Tex., Co-Chairman.

Indiana State Medical Association, French Lick, Oct. 19-21. Mr. James A. Waggener, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave., Madison 5, Wisconsin, Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Sept. 28-Oct. 1. Dr. W. H. Algie, 825 North 7th Street, Kansas City, Kans., Secretary.

Kentucky State Medical Association, Brown Hotel, Louisville, Sept. 22-24. Dr. Bruce Underwood, 620 South Third St., Louisville 2, Secretary.

Michigan State Medical Society, Pantlind Hotel and Civic Auditorium, Grand Rapids, Sept. 23-25. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Secretary.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Obstetrics and Gynecology, Buenos Aires, Argentina, Oct. 26-31.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan American Medical Women's Alliance, Beekman Towers Hotel, New York, N. Y., Sept. 24-Oct. 1. Dr. Ina Marsh, 140 Linwood Ave., Buffalo, N. Y., U. S. A., Registration Chairman.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Regional Meeting, American College of Physicians, San Juan, Puerto Rico, Oct. 15-17. Dr. R. Rodriquez-Molina, Veterans Administration Center, San Juan, Puerto Rico, Governor.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination*. Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Arizona:* *Examination*. Phoenix, Oct. 22-23. *Endorsement*. Phoenix, Oct. 24. Executive Secretary, Mr. Robert Carpenter, 401 Security Bldg., Phoenix.

Arkansas:* *Examination*. Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Reciprocity*. Denver, Oct. 13. Final date for filing application was Sept. 14. *Examination*. Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular*. *Examination*. New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic*. Derby, Nov. 10-11. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

Florida:* *Examination*. Jacksonville, Nov 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: Chicago, Oct. 6-8. Superintendent of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Iowa:* *Examination*. Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination*. Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination*. Lansing, Oct. 14-16. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Minnesota:* Minneapolis, Oct. 20-22. Sec., Dr. E. M. Jones, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity*. Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Missouri: Kansas City, Oct. 22-24. Ex. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: Helena, Oct 5. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination*. Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* Reno, Oct. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Jersey: *Examination*. Trenton, Oct. 20-23. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Oct. 12-13. Santa Fe. Sec., R. C. Derbyshire, 227 E. Palace Ave., Sante Fe.

New York: *Examination*. New York, Syracuse, Buffalo and Albany, Oct. 6-9. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

North Carolina: *Reciprocity*. Asheville, Oct. 12. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination*. Grand Forks, Jan. 6-9, 1954. *Reciprocity*. Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination*. Columbus, December. *Reciprocity*. Columbus, Oct. 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Reciprocity*. Portland, Oct. 16-17. Sec., Dr. Wilmot C. Foster, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination*. Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination*. Providence, Oct. 1-2. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity*. Columbia, Sept. 21. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination*. Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination*. Memphis, Sept. 30-Oct. 1. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

West Virginia: Charleston, Oct. 19. Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Reciprocity*. Madison, October. *Examination and Reciprocity*. Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: Cheyenne, Oct. 5. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arkansas: *Examination*. Little Rock, Oct. 6-7. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Connecticut: *Examination*. New Haven, Oct. 10. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

District of Columbia: *Examination*. Washington, Oct. 19-20. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida: *Examination*. Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Iowa: *Examination*. Des Moines, Oct. 13. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination*. Detroit and Ann Arbor, Oct. 9-10. Sec., Mrs. Ann Baker, 410 W. Allegan St., Lansing.

Minnesota: *Examination*. Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

Nebraska: *Examination*. Omaha, Oct. 6-7. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada: *Examination*. Reno, Oct. 6. Sec., Dr. Donald G. Cooney, Box 9005, University Station, Reno.

New Mexico: *Examination*. Santa Fe, Oct. 18. Sec., Mrs. Marguerite Cantrell, Box 1592, Santa Fe.

South Dakota: *Examination*. Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination*. Memphis, Sept. 23-24. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination*. Dallas and Galveston, October. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination*. Madison, Sept. 19. Final date for filing application is Sept. 11. Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

* Basic Science Certificate required.

DEATHS

Woglom, William Henry ⊕ Teaneck, N. J.; born in Brooklyn Sept. 13, 1879; Columbia University College of Physicians and Surgeons, New York, 1901; assistant in pathology at the Long Island College Hospital in Brooklyn, 1907-1908; pathologist and bacteriologist for the department of health of New York City, 1908-1909; from 1909 to 1912 assistant in cancer research at Columbia and in 1911-1912 served as assistant to the director of the Imperial Cancer Research Fund in London; from 1912 to 1917 assistant professor of cancer research, Institute of Cancer Research at Columbia University College of Physicians and Surgeons, where he was an associate professor from 1917 to 1946, when he became professor emeritus; in 1936 received a medal from Columbia University for conspicuous alumni service; an Affiliate Fellow of the American Medical Association; in 1937 president of the American Association for Cancer Research, of which he was at one time vice-president, for many years a member of the council, and secretary-treasurer; past president of the New York Pathological Society; member of the American Association for the Advancement of Science, Society of Experimental Biology and Medicine, and the Holland Society; an associate of the Royal Photographic Society of Great Britain; member of the scientific advisory committee of the International Cancer Research Foundation from 1941 to 1946; author of "Discoverers for Medicine" and several monographs on cancer; translated several technical books to English from French and German, including "Riddle of Cancer"; for many years editor of the *Journal of Cancer Research*; died in Columbia-Presbyterian Medical Center in New York City Aug. 8, aged 73, of cancer.

Kirkwood, Robert Carnahan, Hampton, Va.; Jefferson Medical College of Philadelphia, 1908; died in Veterans Administration Hospital May 24, aged 66, of coronary thrombosis.

Kushell, Maria Dora, New York City; University of Kharkov Faculty of Medicine, Russia, 1918; affiliated with Gouverneur and Manhattan General hospitals; died in Beth Israel Hospital July 16, aged 59, of cancer.

Laurent, Francis Victor, Maitland, Fla.; Baltimore Medical College, 1908; died May 20, aged 76, of bronchopneumonia and carcinoma of the prostate.

Leitschuh, Linus Frederick ⊕ Winsted, Minn.; University of Minnesota Medical School, Minneapolis, 1938; served during World War II; died in St. Mary's Hospital, Minneapolis, June 28, aged 41, of hepatitis and esophageal varices.

McLarand, Kenneth Carl ⊕ Santa Monica, Calif.; State University of Iowa College of Medicine, Iowa City, 1936; on the staffs of Long Beach (Calif.) Hospital and Santa Monica Hospital; died April 16, aged 47.

McLeod, James Lawrence ⊕ Grand Rapids, Minn.; University of Manitoba Faculty of Medicine, Winnipeg, Canada, 1926; state senator in 1935-1936; affiliated with Itasca Memorial Hospital, where he died June 8, aged 52, of cardiac decompensation and pulmonary embolism.

Malick, Ada Luella, Piqua, Ohio; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died June 30, aged 78, of heart disease.

Morgenthaler, Sophia, Daytona Beach, Fla.; New York Medical College and Hospital for Women, Homeopathic, New York, 1894; died June 25, aged 56, of organic heart disease.

Morris, Joseph Bowman, Punxsutawney, Pa.; Jefferson Medical College of Philadelphia, 1886; died in Adrian Hospital May 25, aged 92, as the result of a fall.

Murchie, John Talmadge, Portsmouth, Ohio; Rush Medical College, Chicago, 1921; died in Broward General Hospital in Fort Lauderdale, Fla., May 26, aged 60, of bronchogenic carcinoma of the right lung.

Neves, Carl Albert ⊕ Custer, S. D.; Atlanta College of Physicians and Surgeons, 1910; formerly manager, Veterans Administration Center, Hot Springs, died in Veterans Administration Hospital in Fort Snelling, Minn., June 28, aged 66, of bronchogenic carcinoma of the right lung.

Neville, J. C. ⊕ Register, Ga.; Medical College of Georgia, Augusta, 1900; on the staff of Bulloch County Hospital, Statesboro, where he died June 22, aged 80, of injuries received in an automobile accident.

Newsom, Goebel William, Fort Pierce, Fla.; Kansas City (Mo.) University of Physicians and Surgeons, 1929; died May 15, aged 53, of arteriosclerotic heart disease and hypertension.

O'Neill, Silverton Hollingsworth ⊕ Blue Hill, Neb.; College of Physicians and Surgeons, Baltimore, 1907; died June 3, aged 76.

Pember, Clyde Harry, Van Nuys, Calif.; American Medical College, St. Louis, 1898; served during World War I and received the Distinguished Service Cross, Croix de Guerre and the Purple Heart; served on the staffs of various Veterans Administration hospitals; died in Veterans Administration Center in Los Angeles, June 22, aged 80, of coronary thrombosis.

Perry, Henry Ernest ⊕ Newberry, Mich.; Michigan College of Medicine and Surgery, Detroit, 1897; Northwestern University Medical School, Chicago, 1904; past president of the Michigan State Medical Society, Luce County Medical Society, and the Upper Peninsula Medical Society; veteran of the Spanish-American War; formerly affiliated with the Newberry State Hospital; served in the state legislature, 1933-1934; died in Lakeland, Fla., July 9, aged 87, of uremia and arteriosclerotic heart disease.

Putnam, John Lancaster, Lebanon, Ky.; Kentucky School of Medicine, Louisville, 1906; served during World War I; affiliated with Mary Immaculate Hospital, where he died July 7, aged 70, of coronary thrombosis.

Quinn, William Blanck, Jackson Heights, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1926; served during World War II; affiliated with Manhattan General Hospital in New York City; died July 15, aged 52, of a heart attack.

Ramsdell, Robert Leroy ⊕ Austin, Texas; University of Texas School of Medicine, Galveston, 1913; past president of the Dallas County Medical Society; formerly on the staff of the Austin State Hospital; affiliated with Central State Hospital at Norman, Okla.; died in Ardmore, Okla., July 5, aged 71, of cerebral hemorrhage.

Randall, Auvigne Mason ⊕ Ashby, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1903; on the staff of St. Luke's Hospital; died June 20, aged 72, of coronary occlusion.

Reeve, Edward A. Tanner ⊕ Elbow Lake, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1897; died June 5, aged 79, of carcinoma of the sigmoid.

Rice, Thompson R. ⊕ Petersburg, Ind.; Hahnemann Medical College and Hospital of Philadelphia, 1892; an Associate Fellow of the American Medical Association; died in St. Mary's Hospital, Evansville, May 9, aged 88, of intestinal obstruction and arteriosclerotic heart disease.

Richardson, John Purver ⊕ Ellensburg, Wash.; Medical College of the State of South Carolina, Charleston, 1919; fellow of the American College of Surgeons; administrator of the Ellensburg General Hospital, where he died July 4, aged 60, of heart failure.

Rooney, Eugene Francis ⊕ New York City; St. Louis University School of Medicine, 1923; specialist certified by the American Board of Pediatrics; served during World War I; director of pediatrics and past president of Misericordia Hospital; affiliated with St. Vincent's Hospital; past president of New York Foundling and St. Clare's hospitals; died in East Northport July 16, aged 57, of acute coronary occlusion.

Rosenfeld, Sydney Cyril ⊕ Chicago; Chicago Medical School, 1937; affiliated with the American Hospital, where he died July 25, aged 46, of multiple sclerosis and terminal bronchopneumonia.

Shafer, John Walter ⊕ Lafayette, Ind.; Rush Medical College, Chicago, 1900; served during World War I; for many years member of the city council; president of the Morocco State Bank; affiliated with St. Elizabeth's Hospital and the Lafayette Home Hospital, where he died July 10, aged 80, of coronary occlusion.

Smith, Francis Michael ⊕ Vicksburg, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; for many years county health officer; formerly health officer of Pine Bluff and of Jefferson County in Arkansas; died July 22, aged 74, of arteriosclerotic heart disease.

Smith, Morton Hartman, Hughesville, Pa.; Medico-Chirurgical College of Philadelphia, 1897; died in Muncy (Pa.) Valley Hospital July 5, aged 79, of coronary occlusion.

Sprague, Emory Russell, Rochester, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1904; died July 4, aged 75, of coronary occlusion.

Tinley, Mary Louise ⊕ Council Bluffs, Iowa; Omaha Medical College, 1895; member of the American Academy of General Practice; affiliated with Jennie Edmundson Hospital and the Mercy Hospital; named "Woman of the Year" in March, 1953, by the Women's Division of the Chamber of Commerce, and was awarded a gold inscribed bracelet; died July 24, aged 84, of heart disease.

Townsend, Junius M., Morton, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; died July 13, aged 74, of injuries received in an automobile accident.

Turchi, John Dominic ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1923; affiliated with Misericordia Hospital; died in the Graduate Hospital of the University of Pennsylvania July 13, aged 53, of pneumonia and cerebral vascular accident.

Ullman, Julius ⊕ Buffalo; University of Buffalo School of Medicine, 1893; an Associate Fellow of the American Medical Association; formerly on the faculty of his alma mater; fellow of the American College of Physicians; died Aug. 14, aged 81.

Waterbury, D. Elliot, Melbourne, Fla.; Chicago College of Medicine and Surgery, 1913; died July 23, aged 91, of cerebral hemorrhage and arteriosclerosis.

Wedekind, Robert ⊕ Louisville, Ky.; Hospital College of Medicine, Louisville, 1897; died recently, aged 82, of myocarditis and arteriosclerosis.

Weimer, Edgar Stanley ⊕ Clearwater, Fla.; University of Pittsburgh School of Medicine, 1910; specialist certified by the American Board of Ophthalmology; fellow of the American College of Surgeons; served during World War I; formerly affiliated with the U. S. Public Health Service; died in St. Petersburg July 5, aged 68, of chronic nephritis.

Whitbeck, Sherwood Volkert ⊕ Hudson, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1901; fellow of the American College of Surgeons; on the staff of the Columbia Memorial Hospital, where he died July 23, aged 73, of Parkinson's disease.

Williams, Aubrey H. ⊕ Denver; Gross Medical College, Denver, 1896; formerly on the faculty of the Denver and Gross College of Medicine, and the University of Colorado School of Medicine; died in the Mercy Hospital July 15, aged 83, of fracture of surgical neck of right femur.

Wilson, Robert Patterson Clark, Platte City, Mo.; Ensworth Medical College, St. Joseph, Mo., 1900; superintendent of the Missouri State School in Marshall; died in Marshall July 12, aged 77, of coronary occlusion.

Yates, Oscar Raymond ⊕ Suffolk, Va.; Medical College of Virginia, Richmond, 1916; past president and vice-president of the Seaboard Medical Association; formerly member and chairman of the school board; active in Boy Scout work and in December, 1948, received the Silver Beaver Award presented by the Old Dominion Area Council of Boy Scouts, of which he was a member; served during World War I; chief of staff at Louise Obici Memorial Hospital, where he died July 15, aged 62, of coronary thrombosis.

York, Charles E. ⊕ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1917; affiliated with Illinois Masonic Hospital, where he died July 21, aged 64, of acute myocardial infarction.

AUSTRALIA

The Commonwealth Medical Benefits Scheme.—The final phase of Australia's answer to the socialized medical schemes of Britain and New Zealand was put into operation July 1. The underlying principle of the Commonwealth Medical Benefits Scheme is the support from government funds of voluntary insurance against the costs of professional services. The Commonwealth Health Department has published a schedule of payments that will be made for a comprehensive range of medical services. A "medical benefits" organization must make a benefit available that at least equals the government subsidy.

The patient pays the professional fee, then sends the receipt to the medical benefits organization, which reimburses the patient for about 90% of the fee. The reimbursement is in two halves. One-half is the organization's own benefit and the other half is the government subsidy for the services involved. The organization then, in turn, files a claim with the government fund for the subsidy. No government subsidy is payable, however, unless the patient is a "financial" subscriber to a medical benefits fund. An aspect of this scheme that differs from American prepaid plans is that the Australian scheme covers the cost of "office" medical consultations and domiciliary visits by the general practitioner.

Advantages of this scheme are said to be as follows: 1. It encourages the principle of self-help. 2. It makes use of voluntary organizations to provide the administrative machinery. 3. It preserves the confidential doctor-patient relationship. 4. There is free choice by the patient of hospital, general practitioner, and specialist. The only duty imposed on the physician is to make out an itemized account in accordance with the government fee schedule, to facilitate payment of claims both by the organizations and the government. Unlike the United States where Blue Shield and Blue Cross plans are separate, most organizations in Australia cover both hospital and medical benefits. The largest organization in Australia is the "Medical Benefits Fund of Australia," which is sponsored by the medical profession. All medical benefits funds must be approved by the government, and a list of approved organizations is published in the daily press.

Following is an example of how the medical and hospital benefits scheme works: For purposes of monetary comparison, nine shillings in Australian money is equivalent in exchange value to one United States dollar. In relation to the costs of living and services, however, average costs and incomes are about double in America compared to Australia. Mr. A. has a wife and three children under 17 years of age. He takes out a maximum policy for both hospital and medical benefits. He pays 3s. (33 cents) each week for each of the hospital and medical benefits, totaling 66 cents weekly. This covers himself, his wife, and an unlimited number of children under 17, so that if his wife should have twins, his premium will not increase. If his wife consults a physician of her choice at his office, she will pay the physician 15 shillings ($1.66). She sends the receipted account (which reads "consultation 15s.") to the medical benefits fund. She receives a refund of 13s. 6d. from the fund, made up of 7s. 6d. from the fund, and 6s. from the government subsidy. If she is found to require an appendicectomy, she will go to a hospital of her choice where she will occupy a room at a cost of £14.14 per week. She stays in hospital two weeks. The account for her hospital room will be £29.8. Before she receives the account, however, it will have had 8s. per day deducted from it. This is a Commonwealth subsidy, which originated in 1946. It is paid directly to the hospital and the payment is made irrespective of whether the patient is a contributor to the medical benefits fund or not. This leaves a balance of £23.16 to be paid by Mrs. A. When she pays the account, she receives a certificate of hospitalization from the hospital, which she presents, with the receipted account, to the medical benefits fund. The fund repays £8.8 per week (£16.16) from its own resources, plus 4s. per day on behalf of the Commonwealth. This latter is a special extra benefit payable only to subscribers to the medical benefits organization. These two payments total £19.12, leaving a balance of £4.4 to be paid by Mrs. A. She will also receive an account from the hospital for operating room fees. There is no government subsidy for this but the medical benefits fund will repay £2.2 of this fee. The surgeon's fee will be about £17.17 for the operation and normal after-care. Mrs. A. will pay the account, which will state "Item 14 Appendicectomy." The receipted account will be sent to the medical benefits fund which will pay £9.7.6 from its own funds, and £5.12.6 on behalf of the government, totaling £15.15. The anesthetic fee will be similarly met on a basis of £1.17.6 from the fund and £1.2.6 from the government.

The public response to this scheme has been almost overwhelming, especially to the Medical Benefits Fund of Australia that is sponsored by the medical profession. The council of the British Medical Association has asked its members not to increase their fees until the scheme has been established for several years. This is to avoid political repercussions and embarrassment to the Liberal party in power that introduced the scheme. It will be remembered that the nationalized medical scheme which the Labor party endeavored to introduce in 1949 was a failure because of the refusal of the physicians to take part in it.

The Labor party today, therefore, is anxious to obtain political capital to discredit the present development, and that is why physicians are anxious to avoid any criticism of what they consider is the ideal solution to the problem of the cost of medical care.

No report of the Commonwealth Medical Benefits Scheme would be complete without a tribute to Sir Earle Page, the Minister for Health in the Commonwealth government, an outstanding surgeon, and a fellow of the Royal College of Surgeons, whose herculean efforts have been rewarded with the fruition of the final phase of this scheme of medical and hospital care.

ISRAEL

University Medical Library.—The circulating library for students opened at the Hebrew University-Hadassah Medical School some months ago contains 1,400 volumes, and additional gifts of books are frequently received. Most of the books have been presented by American-Jewish physicians, and a large collection has been sent by Dr. Louis Wolfson of Boston. The initiative in providing textbooks for the medical students was taken by the Phi Lambda Kappa medical fraternity of the United States, which is headed by Dr. Morton J. Robbins and Dr. M. M. Glazier. Many large American publishing firms have sent gift copies of their medical publications to the library. A collection of medical works presented by Dr. Walter Levy, a New Orleans surgeon, has been shipped to Israel by the Hadassah Chapter of that city, and part of this collection will be placed in the students' library. Sixty volumes on osteology have been presented by the Zionist Federation of South Africa. The opening of the lending library largely has solved the problem of providing medical students with necessary textbooks, which are very expensive.

American Students for the Medical School.—A limited number of students from the United States are to be admitted to the Hebrew University-Hadassah Medical School, according to a recent decision. The candidates must possess the same qualifications as are required by recognized American medical schools. The Jerusalem medical school will enroll candidates who have completed their premedical training in the United States, who have an adequate knowledge of Hebrew, and who have declared their intention of settling in Israel on completion of their studies.

Mass Immigration and Health Conditions.—In a review summarized in *Dapim Refuim*, May, 1953, Dr. Nassau reported on the "Mass Immigration and Health Conditions of the Old

Resident and New Population" in Israel. More than 200,000 children under 14, including 80,000 infants, have entered Israel during the great wave of immigration (1948-1952). The general health of the children of the resident population has not been affected by this immigration. No important damages of the general standard of nutrition have been observed. Among the children of the old residents, no deficiency diseases have been observed. The children of the new immigrants, on the other hand, suffered severe impairment, which was intensified because the health of some of them had already been damaged before or during their trip to Israel, as well as in the large immigrant camps. The rate of mortality at the pediatric wards increased threefold: 80 to 90% of the deceased children were new immigrants from the Middle East and Africa. The damages were in part due to (*a*) ignorance of proper child care and (*b*) the conditions under which the immigrants had to live, first in the immigrant camps and later in the transit camps.

The rate of childbirth is three times higher among immigrants from the Middle East than among the resident population. The Middle Eastern infants have no diseases due to the Rh factor, as the incidence of Rh-negative women from Yemen and Irak is very low (1 to 2%). The weight and body-length of these newborns is considerably less than of those in the resident population. The infant mortality rate rose among those of the transit camps in 1950 up to 15.7%; in 1951 it was still 8.2%, whereas the mortality in the cities was at the same period 3% and in the communal settlements 1.6%. The main causes of death among these infants were diseases originating from acute states of dystrophy. These dystrophies are again to be attributed to the ignorance of the mothers in questions of infant care and feeding. The infectious diseases that appeared most frequently at the transit camps were trachoma, favus, scabies, and infestation with lice. The children of the resident population were almost unaffected by these diseases. The number of new cases of schistosomiasis is (in spite of the great number of persons affected [20,000 to 30,000]) insignificant. A more serious problem, which also touches the children of the resident population, is the wide spread of worm infections.

Infectious diseases of the intestines such as typhoid, paratyphoid, and dysentery, affect almost exclusively new immigrants. Scarlet fever, acute hepatitis, and poliomyelitis were more frequently observed among the children of the old residents. There was a notable increase of diphtheria owing to the interruption of the vaccination during the period of the poliomyelitis epidemic. There are few cases of congenital syphilis. New cases of tuberculosis among the children of old residents and immigrants are rare. Only malaria, from which many of the newcomers are suffering, represents a latent danger to the resident population, though up to now there has been no increase in the number of new cases of malaria. Generally speaking, the mass immigration has not affected the general health of the resident population. The children of the newcomers have suffered severely owing to environmental conditions. Improvement of living conditions, teaching, and prophylaxis will make it possible to eliminate the still-existing dangers.

ITALY

Medical Days in Montecatini.—"Medical Days," organized by the management of the Montecatini Health Resort, were held in that city on May 16-17 for the sixth year. About 500 Italian internists and many guests from abroad were present. Prof. Cesare Frugoni, from the University of Rome and chief consulting physician of the resort, welcomed the guests and emphasized the importance that the Montecatini days are assuming in the cycle of Italian medical conventions. He then announced the topics to be discussed by two young Italian clinicians, Professor Cassano, director of the University of Pisa medical clinic, and Professor Coppo, director of the University of Modena medical clinic.

Since both topics dealt with factors that alter metabolism, Professor Frugoni pointed out the marked changes that modern life has produced in the diet of man, changes that disrupt his normal biochemistry and metabolism. To keep the metabolism normal, modern dietetics aims at a perfect balance between the caloric components (protein, lipids, and carbohydrates) and the noncaloric components (vitamins, water, and salts).

The numerous studies that have been made of the diet of the 2½ billion people of the world show that a large number of them have incongruous and poor diets; on the other hand, many persons eat more calories than they need, and they eat more food, especially lipid-containing foods, than they need.

Considering the damage that prolonged diet imbalances may produce, much of mankind is potentially ill from the standpoint of dietetics. Gillman's studies have clarified the ratio that exists between the frequency and the seriousness of liver alterations that occur in states of hyponutrition. The results of hypernutrition are just as severe, however, and among them are the steatosic alterations of the liver. These are today believed to play an essential part in development of cirrhosis of the liver that is due to disturbed nutrition.

Gastrocardiac Syndromes.—Professors Cassano, Tronchetti, and Bastieri discussed gastrocardiac syndromes. Professor Cassano said that every day it is common to observe some patients who complain of dyspeptic disturbances and who then are found to have heart disease. Cardiovascular disturbances that have their origin in the digestive system are common. The gastrocardiac syndromes seem to be closely related to a more general group of conditions related to the abdomen and the circulatory system, including syndromes involving the liver, gallbladder, and heart or the pancreas and the circulatory system. Careful examination of the morbid signs and diligent study of the physiopathological aspects, however, reveal that the gastrocardiac syndrome is quite distinct from the other syndromes involving the abdominal organs and the heart, even though there are many variants.

The gastrophrenic syndrome should not be classified as a gastrocardiac abnormality; it closely resembles the gastroanginal syndrome. Also the anginal syndrome caused by slight alimentary anaphylaxis should not be considered a gastrocardiac syndrome; the abdominal and cardiac distress in this illness is caused by hyposphyxia. The entire clinical picture, humoral and hemodynamic, can be reproduced by hypodermic injection of histamine in patients in whom liver disturbances resulted in an anaphylactic crisis with particular repercussions on the cardiovascular system.

A real gastrocardiac syndrome is present when a gastric alteration, that is, a true functional disturbance, can be demonstrated. The first manifestation of gastrocardiac abnormality is the hiatus syndrome in which an abdominal disturbance causes painful symptoms that can be related to the heart. The abnormally large hiatus and the consequent diaphragmatic hernia represent the abdominal source of conditions that affect the heart and the circulation.

Other gastrocardiac syndromes are closely related to aerophagy. The most typical aspect of this abnormality is the angor crisis of Roemheld's gastroanginal syndrome and its twin syndrome, paroxysmal tachycardia with gastric and respiratory complications (Rosenbach's syndrome). In both these syndromes there is a constant and typical critical change of the general hemodynamics, with fall of the systolic arterial pressure and especially the mean dynamic pressure and noticeable drop of the venous pressure.

The precordial sensation of constriction, the respiratory anguish, and the painful radiations create the sensation of angina pectoris in the patient. The physician has, therefore, the difficult task of recognizing the various aspects of the painful crisis and of distinguishing what is really anginal from what pertains to phrenic, gastric, and abdominal symptomatology. When the anginal nature of the pain has been recognized in the aerophagic patient, the functional character of these crises should be considered. Even though a favorable prognosis is made, it should always be remembered that distress, even functional distress, is always the expression of a phase of myocardial ischemia.

An animated discussion followed Professor Cassano's report. Professor Cassano emphasized that there is only one true angina. Then there are some painful thoracic syndromes, including the gastrophrenic syndromes. There are no false anginas. Lesions of the coronary arteries are common and may or may not become clinically apparent, depending on whether other neurovegetative and metabolic factors intervene.

He proposes the classification of the obscure forms of angina under the term "minor angina," meaning by this a minor coronary entity with a better prognosis than true angina.

Noninfectious Liver Diseases.—Professor Coppo, a clinician from Modena, reported on the etiology of noninfectious liver diseases. His aim was to summarize the latest concepts of the mechanism of onset of many liver diseases. In many points the report represented the results of experiments and clinical observations of the speaker and his associates. In most cases the pathogenesis of liver disease is complex; this report dealt mainly with the metabolism-altering factors.

Discussing liver disease due to blood stasis, the speaker distinguished simple liver congestion, liver congestion with frank dysfunctional syndrome and often manifest jaundice, and cirrhosis or sclerosis of the liver.

Liver diseases that are due to bile stasis are often associated with infection of the biliary pathways. The pathogenetic mechanism of cholestatic liver disease is very complex. The speaker believes that, in addition to the inflammatory and mechanical factors, the repercussions produced on the digestive system by the absence of bile in the small intestine should be taken into consideration.

Liver diseases caused by altered protein metabolism are mainly due to lack of proteins. Altered metabolism of proteins and amino acids is an important pathogenetic factor of common cirrhosis. Hepatic alterations entirely similar to those produced by lack of proteins have been observed in patients with pellagra. Primary and secondary amyloid liver diseases are also included in this group.

Among the liver diseases associated with an altered carbohydrate metabolism, the speaker distinguished diabetic liver abnormalities from abnormalities due to glycogenesis (Gierke's disease). This is accompanied by surplus of liver glycogen that is produced by an altered metabolism.

Liver diseases associated with disturbances of fat metabolism assume various characteristics, depending on whether the steatosis and the accumulation of fats in the liver take place when there is a generalized lipidosis or when only the liver becomes filled with fats. In many cases, according to the speaker, liver steatosis constitutes one phase of the cirrhogenous evolution of the liver.

The speaker discussed also liver diseases associated with conditions caused by a deficiency of vitamins or hormones, those due to allergy and exogenous toxic factors, those of splenic origin, and those that develop during pregnancy. The hypothalamus seems to play an important role in liver diseases associated with nervous lesions; these are rare syndromes but they have great importance.

LONDON

Tuberculosis in Shoemakers.—A mass radiography survey of factory workers in Northamptonshire, the center of the shoemaking industry in Great Britain, revealed in 1947 a disturbingly high incidence of pulmonary tuberculosis in boot and shoe factories. Mortality figures indicated that the death rate for pulmonary tuberculosis was higher among "boot and shoe factory operatives" than among "makers and repairers" (nonfactory workers). These findings led to an intensive investigation, the results and implications of which are reviewed by Dr. Alice Stewart of the social medicine unit of the University of Oxford (*Brit. J. Tuberc.* **47**:122, 1953). The results can be summarized as follows: The relative excess of tuberculosis in the boot and shoe industry as a whole is due to the presence of an exceptionally large number of tuberculosis carriers in the working population. The unequal distribution of cases within the industry is due to the fact that in large workshops the spread of infection from carriers to fellow-workers is greater than in small ones. Since, for men, shoemaking is a relatively light occupation, it attracts more persons with established tuberculosis than most industries and allows them to remain at work much longer than if the work were really strenuous. Provided the men with chronic tuberculosis work on their own, as do most shoe repairers, no communal harm is done, but if, as is the case of boot and shoe factory workers, they work in large groups, the disease is spread to others. To account for the opposite trends of mortality among shoemakers and printers, it is "postulated that the migration of operatives from cottage workshops to factories, which is a feature of every industrial revolution, is liable to provoke a relatively slow rise in the tuberculosis death rate followed by a subsequent fall (i. e., a slow-motion epidemic). Provided, therefore, there is in any trade a nucleus of carriers, the date of its industrial revolution determines whether its tuberculosis death rate, relative to the national rate, is rising, falling or remaining stationary." In the shoemaking industry the factory system developed relatively late (1900-1914). From the data collected in this investigation it is suggested that, for every 10 boot and shoe operatives who contracted pulmonary tuberculosis from a relative, there were 18 to 20 who probably contracted it from a fellow-worker, and that for a shoemaker working in a room with about 200 other workers the risk of contracting tuberculosis is over three times as great as for a shoemaker working on his own.

Among the implications of this investigation, stress is laid on the fact that "spread of tuberculosis in factories is a greater menace to the community than spread in the home. . . . If the 'pressure head' of infection really lies in the factories, then our present policy of encouraging tuberculous subjects to return to industry as soon as they are fit is wrong and should be replaced by one in which tuberculous persons, while given every other consideration, are forbidden to mix with other factory workers. . . . In fact the only social remedy that could be relied upon to free the factories from infection would be 'a modified form of sanatorium treatment' for all tuberculous workers." Finally, it is stated that none of the studies described in this report "supports the view that shoemaking should be scheduled as a 'dangerous' occupation."

The Present Status of Cancer Research.—The present status of cancer research was recently reviewed by Prof. Alexander Haddow, director of the Chester Beatty Research Institute, Royal Cancer Hospital, in moving the adoption of the annual report at the 30th annual meeting of the British Empire Cancer Campaign. Until recently, little or nothing was known of the mode of action of carcinogenic agents. Lately, increased attention has been given to the biochemical action of these agents, and for the first time "in the case of certain cancer cells we have now recognized the imprint left upon them by the chemical agents which induced their appearance." The field of interest is being widened and now includes studies of the colloidal and molecular organization of the chromosomes. "Although we are not finally sure, it appears that the end result of such interference [i. e. with the chromosomes] may be a genetical and enzymatic deficiency—in other words, that the cancer cell is derived from the normal cell through the loss of enzyme or ferment systems normally responsible for growth regulation. While much remains to be done, I would hazard the prediction that sooner or later, depending on our efforts, we shall see in the chemotherapy of cancer something entirely new, namely a kind of substitution therapy by which the cancer cell will be controlled from without, by the same kind of chemical means in virtue of which the normal cell automatically regulates itself from within. While we cannot penetrate the future, the prospects have sensibly changed, and even cancer prevention, which only a few years ago seemed utterly beyond our hopes may yet prove to be within our ultimate powers."

He suggested that the history of cancer research may well resolve itself into three main phases: (1) the impartial exploration of every avenue of attack; (2) the definition and limitation of those few approaches that are decisive in strategy; and (3) a phase of conscious development. We may shortly be moving from the first of these phases to the second. "If the third phase is still beyond our ken, it may not elude us so very long. Although many biological paradoxes and puzzles have still to be solved, and many fantastic difficulties have yet to be overcome, the great fundamental principles, almost certainly of startling simplicity, are sure to emerge. It is then that we shall enter the phase of development." When this phase comes, "It will very likely partake of the nature of biological engineering on a vast scale, and may demand vast expenditures far in excess of those we have hitherto disposed of." His final summing up was, "More than half-way through the twentieth century, after fifty years of cancer research in its modern sense, and after thirty years of concerted and ever-intensifying effort by the Campaign, it seems we are now at last approaching 'the end of the beginning'."

General Practitioners and Cancer Propaganda.—Earlier this year the British Empire Cancer Campaign sent a one-question questionnaire to every general practitioner in the United Kingdom: "Do you consider that the launching of a scheme of lay educational propaganda on cancer (by pamphlet, lectures, films, etc.) would be of assistance in securing the earlier diagnosis of cancer and thereby improving the chances of a cure?" To the 21,040 letters sent out, 5,053 replies were received, i. e., a 24% response. Of the replies, 2,148 were an unqualified "yes" and 2,683 an unqualified "no." In view of this strong element of objection among general practitioners to such propaganda, the campaign has decided to take no further action at the moment.

MEXICO

Tenth Anniversary of Children's Hospital in Mexico City.—In April, 1953, several functions commemorated the 10th anniversary of the Children's Hospital in Mexico City. In a public ceremony the founders of the hospital, former President Avila Camacho, former Secretary of Public Assistance, Dr. Baz, and former Undersecretary of Public Assistance, Dr. Zubirán, were honored. In the following days there were a pediatric meeting, a scientific exhibition, and a popular exhibition for medical education purposes.

At the pediatric meeting, which was attended by 458 physicians from all the states of Mexico and from abroad, there were general communications, roundtable discussions, and several seminars. The general communications presented the experience of the hospital in its first 10 years of life. Among the subjects discussed, the nutritional problems, the infectious diarrhea of children, and the acute abdominal conditions of infancy aroused the most interest. The scientific exhibition, which was also presented by the staff of the hospital, had 45 booths, each dedicated to illustration of the problems that are of most importance to pediatricians and general practitioners.

The popular exhibit was visited daily by an average of 12,000 persons. There were 60 booths, in many of which special lecturers explained to the general public different aspects of the care of children. Many booklets were distributed without charge.

Acute Abdominal Conditions in Infantile Diarrhea.—At the meeting on pediatrics, commemorating the 10th anniversary of the Children's Hospital, Drs. Carlos Sariñana, Joaquín de la Torre, and Arturo Fonseca, from the departments of surgery and medicine, reported their experience with 33 patients under 2 years of age who had an acute abdominal condition following an attack of diarrhea. Twenty-three (69.5%) were under one year of age, the youngest being only 13 days old. The diarrhea was considered severe in 79% of the cases, and in 76% blood was found in the stools; it appeared during the second week in almost half of the cases.

In every case there was abdominal distention and vomiting. In only one-third of the cases was intense spasm found, and in 80% constipation appeared together with the acute abdominal symptoms. The most frequent complication was bronchopneumonia, which was present in 45% of the cases. Stool cultures were done on 20 patients, with positive results in 11. Organisms of the colon and paracolon group were isolated in six, including coli 3 Kauffman in one, Shigella flexneri in two, Proteus morganii in one, Pseudomona aeruginosa in one, and Salmonella typhi and Endamoeba histolytica in one. Roentgenograms of the abdomen showed dilated loops, fluid levels, and thickened intestinal walls. In cases of perforation free air was found in the subdiaphragmatic space.

Twenty-four of the patients were operated on, with 22 deaths. All of the nine patients not operated upon died. Treatment consisted of use of antibiotics, correction of fluid and electrolyte balance, and administration of blood and plasma.

Autopsy was done in 15 cases, and in 10 more the resected small intestine was studied histologically. In the rest, diagnosis was based on the operative findings. Different types of lesions that caused the acute abdominal symptoms were found at the time of laparotomy or autopsy. These were classified by the authors as follows: 1. Echymotic or necrotic lesions, with circumscribed zones of infarction or pinpoint hemorrhages. The most frequent site was the ileum, followed by the jejunum or colon. In only one case were lesions found in the stomach and duodenum. Some areas were perforated, with evident peritonitis. 2. Extensive zones of intestinal infarction, usually located in the ileum. Thrombosis of the mesenteric vessels proved to be the cause of the infarct in two of these patients. 3. Ulcerations of the small or large bowel of variable depth, and perforation secondary to such ulcerations. 4. Zones of intestinal pneumatosis, usually located in the ileum. 5. Bloody or purulent fluid in the abdominal cavity, found in all of the patients.

The pathology department reported the following findings in the intestine: 1. Edema, congestion, necrotic areas, and in some cases hemorrhages of the mucosa and submucosa. In others, the mucosa had disappeared completely and was replaced by granulation tissue. 2. Round cell or plasma cell infiltration of one or several layers. Sometimes edema and hemorrhage of the serosa and subserosa, with deposits of fibrin and leukocytes, were found. In others, there was complete autolysis with perforation. Peritonitis and mesenteric adenitis were described, as well as alterations in other organs. This, together with the results of the bacteriological studies showing different micro-organisms, led to the conclusion that, in some cases, peritonitis was a manifestation of a septicemia of intestinal origin.

The most important comments referred to the differential diagnosis between truly acute conditions of the abdomen and conditions due to paralytic ileus. The etiology and pathology of the disease are not completely understood, but the authors believe that infection, malnutrition, and increased intra-abdominal pressure are contributing factors in the majority of cases. The surgical procedure most frequently used was the resection of the affected part, with enterostomy.

Medical Meeting at San Luis Potosí.—At the central city of San Luis Potosí, from April 28 to May 2 this year, a regional medical meeting was attended by physicians from all the neighboring states and from Mexico City. Medical meetings like this, called "cycles of medical days," have been held since 1940 and the last one was the fifth. They are sponsored by the University of the State of San Luis Potosí and the Central Hospital and the Society for Medical Studies of the city of San Luis Potosí.

The committee that organized this meeting consisted of Dr. J. M. Torre, Dr. J. E. Sanchez, and Dr. E. Anaya, as president, secretary, and treasurer respectively; all of them are members of the faculty of the university and of the staff of the Central Hospital.

The meeting consisted of (*a*) general communications and symposiums, (*b*) clinicopathological conferences, (*c*) special sections, and (*d*) medical motion pictures. The general communications were presented by members of the major hospitals of Mexico City. They concerned surgery of the mitral valve, by Drs. Chavez, Robles, and Mendoza, from the Instituto de Cardiología; portal hypertension, by Drs. Sepulveda, Villalobos, Rojas, Falomir, Muñoz, and Quijano from the Hospital de Enfermedades de la Nutrición; tumors of children, by Drs. Salas and Contreras from the Hospital Infantil; and endocrine problems in gynecology, by Drs. Alvarez-Bravo, Arzac, and Gómez-Mont.

The section meetings were on endocrinology, cardiology, cancerology, and anesthesiology. Thirty-seven papers were read in all. The clinicopathological reports were presented by members of the local hospital and discussed by the guests. In addition there were clinical rounds, surgical demonstrations, and exhibits of different kinds. The general consensus was that this meeting was very successful and that the comparison of the experience of the local physicians with that of physicians from other cities was very useful.

CORRESPONDENCE

EXPEDITION TO SOUTH AMERICA

To the Editor:—I would like to place before your readers details of a project that might interest them. An expedition has been planned for late this fall. The members of the expedition will drive two sports cars, towing small trailers, down the Pan-American Highway to Rio de Janeiro. We hope to complete the journey entirely under the power of the cars, and, as many readers of THE JOURNAL may know, this is a pioneering venture.

There are three of us at present, an American who is a graduate of Massachusetts Institute of Technology, with motor engineering experience, and two Englishmen who both are Oxford graduates, with some years in the United States, and one who has a master's degree in business administration from Harvard. We need a fourth man to complete the group. As the fourth man we want to recruit a young American medical graduate, preferably with some experience in the tropics. Expenses will be shared but will be low, since the expedition is receiving financial support in return for a photographic record of the journey. Time will be available for study en route so this expedition might be an opportunity that some reader would like to hear about. Further details may be obtained by writing to P. O. Box 1610, Grand Central Station, New York 17.

OBSTRUCTION DUE TO SERUTAN

To the Editor:—Several cases have been reported in which esophageal obstruction resulted from the use of one of the hygroscopic bulk laxatives. In every instance some of the ingested material lodged in the esophagus and formed a tenacious, sticky mass. An additional case seems worth describing, not only as a further warning concerning the use of such laxatives but, particularly, as a report of the prompt response to a method of treatment that, as far as I know, has not previously been tried.

A 72-year-old white man was admitted to the North Carolina Baptist Hospital at 4 p. m. on April 7, 1953, because of an obstruction in the esophagus. For years he had been in the habit of taking Serutan. The manufacturer of Serutan states that it is a hydrogel obtained from Plantago ovata and extracted from sugar beets from which the roughage has been removed. At 10 p. m. on the night before admission the man put 2 teaspoonfuls of Serutan in a glass of water and swallowed the contents of the glass before allowing the powder to dissolve. In a few minutes, he experienced a painful, burning sensation when he attempted to swallow and found that he could not drink a glass of water. Throughout the night he vomited and coughed up what he described as "thick clots of mucus." A physician who was called at 6:30 a. m. gave him an intramuscular injection of 130 mg. (2 grains) of sodium phenobarbital in oil. This made him drowsy, but did not relieve the obstruction. Physical examination at the time of admission was noncontributory. Roentgen examination was not attempted because of the possibility that the barium might add to the obstruction. Since Serutan is a carbohydrate material, it was thought that a starch digestant might dissolve the mass; hence the patient was given 8 cc. of liquid Taka-diastase in half a glass of water, to be sipped slowly. Before the first dose had been completed, the patient said that he felt "the lump melting away" and found that he could swallow without effort. The next morning (April 8) he was able to take a bland meal without difficulty, and he was discharged that afternoon. He made an uninterrupted recovery.

A fluoroscopic examination of the esophagus, with a barium swallow, was made a week later, on April 14. The examiner reported "no obstruction to the flow of barium through the esophagus. . . . There was on deep inspiration a very minimal degree of hiatus insufficiency."

The rapid relief obtained from the liquid Taka-diastase, after more than 20 hours of obstructive symptoms, justifies the supposition that it was effective in liquefying the obstructing mass. Certainly it seems to be worthy of further trial in cases in which esophageal obstruction follows the ingestion of a hygroscopic laxative. Taka-diastase should be used before barium is given since the barium would add to the size of the mass in the esophagus and would also act as a mechanical barrier between the starchy material and the starch digestant.

REMOVAL OF SKIN SUTURES

To the Editor:—I enjoyed the article on removal of skin sutures by Weinstein and Roberts in THE JOURNAL, July 25, 1953, page *1231*. Dr. Daniel L. Borden introduced a similar traction loop into the suture which he reported in the *American Journal of Surgery* (73:100, 1947). I have added one more step. I leave the end of the interrupted sutures long and tie the long ends together, or I use a split buckshot in place of the knot so that all stitches can be removed at once. This saves digging around for each stitch and makes it less likely that a stitch will be missed because the light is poor at the bedside, tissue swelling is present, or the area is inaccessible.

R. H. KAZMIERSKI, M.D.
208 Oak St.
Coudersport, Pa.

To the Editor:—After reading the article "Easy Removal of Skin Sutures," by Drs. Weinstein and Roberts (*J. A. M. A.* [July 25] 1953) we agree with the authors that their suture lift is a valuable method for removing skin sutures. We have found, however, that it is easier to use the eye end of the needle in inserting the lift. This blunt end slips under the stitch easily without piercing the skin. We also tie the loose end of the first knot to the loose end of the last knot so that the suture lift can be easily identified. With these two additions to the technique, we have found the time necessary for insertion of the lift markedly reduced.

Chester Hospital
9th and Barclay Sts.
Chester, Pa.

To the Editor:—In THE JOURNAL for July 25, 1953, page 1231, Weinstein and Roberts describe an easy method of removal of skin sutures. A practically identical method was described by A. P. Hovnanian in *Plastic and Reconstructive Surgery* (8:407 [Nov.] 1951). I have used this method myself during the past year and a half and find it very satisfactory.

ROBERT H. IVY, M.D.
Editor, *Plastic and Reconstructive Surgery*
1930 Chestnut St.
Philadelphia 3.

To the Editor:—In reference to "Easy Removal of Skin Sutures" (*J. A. M. A.* **152**:1231 [July 25] 1953), a very similar method for skin suture removal was described in 1951. The reference is "A Simple Technic for Removal of Fine Interrupted Skin Sutures" (Hovnanian, A. P.: *Plast. & Reconstruct. Surg.* 8:407, 1951).

COUNCIL ON MEDICAL SERVICE

RATING COMMUNITIES

During the past two summers the Council's Committee on Extension of Hospitals and Other Facilities[1] has been making a study of physicians placement activities in a number of states. In these studies the Committee arranged for field visits to various small communities in each state, some of which had obtained a physician recently and others of which had requested a physician but had been unable to attract one. In communities that had been successful in obtaining a physician, questions were asked of the physician and his wife designed to learn why he had located there rather than in some other community in the state. In communities where a physician had not been obtained, an effort was made to learn why the community had been unsuccessful in its efforts to attract a physician.

As a result of the first series of field visits, a list was compiled showing (*a*) the major factors related to a community's need for a physician and (*b*) the primary characteristics determining a community's attractiveness to a physician. The various categories were then assigned a relative importance numerically and an A, B, C scale set up to record point totals. From this it was theoretically possible, on the basis of adequate knowledge, to assign a community an A, B, or C priority rating that would relate to its need for physician as well as its ability to attract one.

This medical priority rating program was then ready for testing in the field. This was done in a second series of field visits to small communities. After talks with physicians in these communities, particularly those who had recently established their practices, and after interviews with community leaders in those places that were still searching for a physician, the data gathered were applied to the priority program and a rating assigned to each community. This rating was then checked against the opinion of the executive secretary of a state medical society or some other qualified person familiar with the medical needs and resources of that community. In nearly every case the evaluation given by one with firsthand knowledge concerning the location coincided with the rating shown by the priority plan.

By means of such testing several revisions were made in the plan. The revised categories and the points assigned to them were reviewed by the Committee on Extension of Hospitals and Other Facilities and the Council on Medical Service and the priority rating program as approved by them is published here for review by physicians and others interested in placement problems.

A MEDICAL PRIORITY RATING PROGRAM

This Medical Priority Rating Program has been prepared and is submitted to the state medical associations with full knowledge of the many differences between states. However, the criteria on which a physician bases his appraisal of the desirability and medical need of a community are sufficiently uniform to permit their adaptation to any state. In such adaptation, the points assigned to items may be increased or decreased to conform to local conditions without altering the basic concept.

Encouraging the state associations to use this program in the operation of their placement service is admittedly an experimental step. At the same time it may well serve several purposes: (1) to stimulate communities to analyze their characteristics and facilities from a physician's viewpoint; (2) to encourage state associations in the collection of a certain minimum amount of information on each opening, and (3) to supply the A. M. A. with a valuable differentiation among the communities in the United States listed as needing a physician.

Objectives

- I. To determine where a need for a physician actually exists and estimate the degree of that need
- II. To evaluate the medical desirability of a given location
- III. To assist communities in improving their medical desirability rating
- IV. To guide physicians in their choice of locations

Need Priority—From the Standpoint of the Community

A..............60 to 105 points
B..............30 to 60 points
C.............. 0 to 30 points

Calculation To Be Based on:

1. Doctor-population ratio
   - 1 active to 1,200 population and under.... 0 points
   - 1 active to 1,200 to 2,000 population......20 points
   - No M.D. or 1 active to 2,000 population and over ....30 points
2. Distance to nearest adequate medical care
   - Within trade area...................... 0 points
   - Inadequate, or not within trade area........25 points
   - (Considered inadequate if 20 or more points are recorded for number 1)
3. Age of physicians serving the area
   - Under 45 years of age.................... 0 points
   - 45 to 60 years of age....................10 points
   - No M.D., one over 60 years of age, or one in limited practice....................35 points
   - (Example: Doctor #1 50 years..10 points
     Doctor #2 33 years.. 0 points
     Average.......... 5 points)
4. Intangible factors ....0 to 15 points
   - A. Need as seen by the inhabitants of the community
   - B. Their willingness to accept the situation
   - C. Any factors which may increase or decrease the need picture as drawn by the above categories

Desirability Priority—From the Standpoint of Physician

A..............70 to 105 points
B..............40 to 70 points
C..............under 40 points

Calculations To Be Based on:

1. Hospital facilities
   - Located in community...................30 points
   - Reasonably accessible to physicians........15 points
   - Not reasonably accessible................ 0 points
2. Office facilities offered by the community
   - Adequate space and equipment offered at low rent or rent free for a given period......25 points
   - Adequate space, no equipment, with rent....20 points
   - No facilities or inadequate ones........... 0 points
3. Opportunity for assured income as health officer, care of the indigent, industrial accounts, etc.
   - Yes ....15 points
   - No .... 0 points
4. Facilities for family life................0 to 25 points
   - If excellent, allow...............25 points
   - If good, allow...................15 points
   - If poor, allow.................. 0 points
     - A. Housing ....0 to 25 points
     - B. Schools ....0 to 25 points
     - C. Churches ....0 to 25 points
     - D. Social opportunities, including golf clubs, fraternal organizations, other professional men in the community, women's organizations ....0 to 25 points
     - A + B + C + D ÷ 4..Average:——
5. Intangible factors ....10 points
   - A. Availability of diagnostic service, consultation and postgraduate education
   - B. Ambulance and nursing service available
   - C. Possibility of time off for vacations and special causes
   - D. Proximity to a large medical center
   - E. Other factors contributing to medical desirability

Needle Liver Biopsy in *Thyrotoxicosis.*—*Biopsy specimens of the liver were obtained with the Vim-Silverman needle in 13 patients with thyrotoxicosis. The anatomical material thus obtained was correlated with the results of hepatic function tests, including the determination of the serum bilirubin, serum gamma globulin, serum proteins with albumin-globulin ratio, cephalin cholesterol flocculation, thymol turbidity, sulfobromophthalein dye excretion, and plasma prothrombin. The authors found that the functional capacity of the liver in thyrotoxicosis is hardly affected or is affected only to a very slight extent and that pathological changes in the liver in this condition are slight except for vacuolization of liver cell nuclei. They believe that the discrepancy between their own observations and those of other investigators, who observed severe anatomical changes in the liver of patients with thyrotoxicosis is due to the fact that the previous authors made their observations on autopsy material exclusively.

Ulcerative Colitis: Giant Ulceration Following Corticoid Therapy.—These observations were made on 14 patients with a severe or fulminating ulcerative colitis who were treated with intravenous administration of corticotropin at the Duke Hospital and on one other patient treated elsewhere. The clinical course of the disease prior to the treatment was classified as fulminating in 11 and as severe in four. Fourteen patients received daily intravenous infusions of 20 units of corticotropin for approximately 12-hour periods for from 4 to 17 days. Twenty courses were given to the 14 patients. Three patients also received corticotropin intramuscularly (80 units per day) for periods of 5 to 13 days, and one patient was treated with corticotropin gel (40 to 80 mg. per day) for a 16 day period prior to intravenous therapy. Cortisone was taken by four of the patients either before or after the course of corticotropin. Antibiotics were administered concurrently. Sustained improvement resulted in eight of the patients subjected to corticoid therapy, while the remaining seven either had only temporary improvement or became worse. Perforation of the colon developed in one patient, and large undermined ulcers developed in four patients who subsequently underwent colectomy. The colectomy specimens showed longitudinal undermined ulcers unaccompanied by significant fibrosis or mucosal regeneration. The sigmoidoscopic appearance of these ulcers and the accompanying roentgenologic changes were distinctly different from what is usually seen in cases of idiopathic ulcerative colitis in which corticoid therapy is not given. Corticotropin and cortisone appear to alter the course of idiopathic ulcerative colitis. Since submission of this paper the authors followed an additional patient, who was observed to have huge linear ulcers, one of which perforated, transecting the entire length of the transverse colon, following intravenous therapy with corticotropin. At autopsy the anterior abdominal wall was adherent to a large open segment of the transverse colon, 27 cm. in length and 5 cm. in width. The anterior wall of the transverse colon appeared to be completely destroyed by the ulcerative process. There was also a localized abscess associated with perforation of the cecum and ascending colon. The remaining colon showed huge, linear ulcers, surrounded by considerable mononuclear inflammatory reaction.

Vitamin E and the Climacteric Syndrome.—Blatt and associates attempted to evaluate the effectiveness of alpha tocopherol therapy in women with menopausal symptoms with the aid of the menopausal index, which gives numerical values to the commonest menopausal symptoms. While in an earlier report the authors employed a menopausal index including 11 symptoms, they now consider only the four most important symptoms, namely, vasomotor symptoms, nervousness, insomnia, and paresthesia. The effect of vitamin E was compared to the effect of two standard estrogens, ethinyl estradiol and conjugated estrogenic substances (equine). In addition, phenobarbital and placebos were used throughout the study, which extended over three years. Vitamin E administered in the form of 50 to 100 mg. of alpha tocopherol acetate a day was no more active than a placebo in the control of menopausal symptoms and proved to be effective in only 25.6% of 82 patients. Placebo therapy proved effective in 33% of 298 patients. Phenobarbital was therapeutically successful in 42.8% of 88 climacteric patients. Ethinyl estradiol, 0.05 mg. a day, and conjugated estrogenic substances (equine), 1.25

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

mg. a day, were comparable in activity and adequately controlled menopausal symptoms in 92.6% and 90.8% of 107 and 173 patients respectively. This failure of vitamin E to exert a therapeutic effect corresponds with its failure to show pharmacological activity experimentally in the absence of vitamin E deficiency.

Lesions of Pancreas in Malignant Hypertension.—Hranilovich and Baggenstoss of the Mayo Clinic say that in a previous study of dilatation of pancreatic acini in patients who died of uremia, they were impressed by the high incidence of other parenchymal lesions in cases in which uremia was the result of nephrosclerosis. Since the parenchymal lesions in cases of nephrosclerosis were usually associated with a severe degree of arteriolosclerosis, it was surmised that most of the parenchymal lesions were the result of vascular changes and could be interpreted as infarcts. This study endeavors to elucidate the relationship between the vascular changes and the various parenchymal lesions. Records of 100 cases of malignant hypertension observed between 1924 and 1948 in which necropsies were performed were obtained from the files of the Mayo Clinic. The clinical charts were abstracted for data referable to age, sex, onset, duration and degree of hypertension; symptoms referable to cerebrospinal, cardiovascular, and renal systems; alterations in chemical constituents of blood and other body fluids, and type of death. The necropsy protocols furnished data concerning weights of the hearts and kidneys and changes in other organs. Gross descriptions of the pancreas were studied in every case. The routine sections of the pancreas were reviewed. The controls consisted of 100 cases in which the sex and the age distribution by decades of life were essentially the same as those in the cases of malignant hypertension. Clinical charts, correspondence, and necropsy protocols in the control cases were used to rule out hypertension and congenital or acquired cardiac disease. Moderate to severe arteriolosclerosis occurred in 68, infarcts of the pancreas were found in 7 cases, focal parenchymal necrosis in 21 cases, and foci of atrophy in 73 of the 100 cases of malignant hypertension. Vascular alterations were the most important factor in the production of parenchymal lesions such as infarction, focal parenchymal necrosis, atrophy, and fibrosis. Although arterial thrombosis could be demonstrated in 6 of the 7 cases of pancreatic infarction, it could not be demonstrated in any of the 21 cases in which parenchymal necrosis was observed. It is probable that congestive cardiac failure and shock may be important factors in the production of parenchymal necrosis in the presence of a severe arteriolosclerosis. Arteriolosclerosis of the pancreas is strongly indicative of, but not pathognomonic for, malignant hypertension. Vascular factors by themselves are not important etiological factors in acute hemorrhagic pancreatitis.

Internal Mammary Coronary Artery Anastomosis.—The anatomical structure of the ventricular myocardium and the pathological conditions existing in coronary heart disease suggested to Vineberg and Miller that an implanted internal mammary artery can bridge the blocked superficial coronary vessels which are still open and free of disease. A new approach to the vascularization of the myocardium was first attempted by them in 1945. As a result of experiments on several series of dogs they concluded that coronary artery disease is limited to the epicardial vessels. The vessels within the myocardium are, for the most part, not diseased. There exists, therefore, within the myocardium, a vast network of patent vessels capable of carrying arterial blood to the myocardium. Fresh arterial blood reaches this network when an internal mammary artery is placed with an open sixth intercostal artery between the myocardial fibers. The authors feel that the estimation of the value of experiments designed to revascularize the myocardium should be based on functional studies. In their experiments they demonstrated that the internal mammary artery after implantation into the myocardium is capable of maintaining the circulation of the left ventricle after complete or partial occlusion of the anterior descending branch of the left coronary artery. These experiments suggested that internal mammary artery implantation might be of value in the treatment of human coronary artery insufficiency. To date nine patients with coronary artery insufficiency have undergone internal mammary artery implantation. The results have been most encouraging and will be published.

New Device for Objective Auscultation of Heart.—In order to register simultaneously the heart acoustics for visual and audible reproduction, three known instruments (eventually to be combined into one unit) are used: the electrocardiograph, the phonostethograph, and the electromagnetic tape recorder. While the limb and chest leads pick up the electrical waves of the heart beats and transmit the magnified waves upon a moving medium, the microphone simultaneously picks up the heart sounds and murmurs. These are first carried to the same moving medium for visual recording of the sound, which is the known electrostethogram; the same sounds and murmurs picked up by the microphone are simultaneously recorded on a sound magnetic tape. This simultaneous visual and aural recording of the heart beats, sounds, and murmurs can be called an audiovisocardiogram. This permanent record can be studied, compared, and discussed at any time. It can be kept on file or shipped anywhere to be examined by a physician who did not examine the patient. The sounds are less distorted, the tape giving higher fidelity than the phonographic disk. The permanent visual and audible record will enable the physician to follow a given disease step by step. In many instances, questionable murmurs become clarified. Any eventual change in the quality of a sound or murmur can be added and compared with those previously recorded. The audiovisocardiogram will reduce the margin of errors so often encountered in auscultation and may prove of value in a variety of medical fields: in rheumatic mitral stenosis, in the surgical treatment of congenital heart disease, and during labor (changes in fetal heart beats could be recorded). The method might prove useful for teaching purposes, in clinics, in induction centers, factories, insurance companies, and in legal medicine.

Hypercholesterolemia, Myxedema, and Atherosclerosis.—Clinical and postmortem findings are reported in five men and three women between the ages of 22 and 63 with rheumatic heart disease or cor pulmonale. They had all survived one to 13 years following total surgical thyroidectomy and had clinical hypothyroidism or myxedema with increased cholesterol values. These patients were generally maintained with basal metabolic rates of approximately -20% by small doses of thyroid. The blood cholesterol levels of these patients averaged 125 mg. above the average pretreatment levels of 170 mg. per 100 cc. Cholesterol values of over 400 mg. per 100 cc were present for many months in some of these patients. Postmortem examinations did not reveal complete occlusion of any of the coronary arteries of these eight patients. Five of the eight showed no narrowing of any of the main stems or branches of the coronary arteries. Only three of the eight showed slight narrowing of one of the main stems. In the other arteries atheromatosis and atherosclerosis varied greatly but were similar to that generally observed in similar euthyroid patients. The authors' observations do not disprove the role of the cholesterol in the production of atherosclerosis. They demonstrate, however, that the hypothyroid state with its hypercholesterolemia is not necessarily and by itself a sufficient etiological factor for the production of coronary atherosclerosis.

Anticoagulant Therapy in Myocardial Infarction.—Bishydroxycoumarin (Dicumarol) alone or bishydroxycoumarin and heparin were given to 100 patients during episodes of acute myocardial infarction. An earlier group of 211 patients receiving conventional treatment but no anticoagulants served as controls. Eighteen of the anticoagulant-treated patients died (a mortality rate of 18%), while 68 of the control group died (a mortality rate of 32%). Patients were classified in prognostic categories according to the following criteria: (1) very poor risks, in whom the attack was the patient's first and shock and diabetes or shock and azotemia were present, or who had had a previous attack and in whom shock was present or congestive failure and diabetes and azotemia were present; (2) poor risks, in whom shock, congestive failure, diabetes, or azotemia was present within the first week of admission; and (3) good risks, in whom none of the concomitant manifestations in group 1 and 2 were present. Anticoagulants failed to improve the mortality rate in the "very poor risk" category. The mortality rate in the "good risk" category was very small with or without anticoagulants. The beneficial effects of anticoagulants were most apparent in the "poor risk" group of patients and then chiefly in those less severely ill. Such beneficial effects cannot be entirely ascribed to a reduction in thromboembolic phenomena, since thromboembolic complications in the authors' experience played a minor role in the course of acute myocardial infarction. The lower mortality rate in these patients treated with anticoagulants was probably due either to some property of these agents in addition to their anticoagulant property or to other entirely unrelated and undetected factors.

Intrauterine Perforation of Meckel's Diverticulum.—The case reported is of interest primarily because one of the complications of Meckel's diverticulum, ulceration and perforation, occurred during gestation and caused the appearance of roentgen findings commonly associated with meconium ileus. Only subsequent postmortem examination, nine hours after birth, disclosed the true nature of the roentgen findings. The specimen of the small intestine showed a diverticulum measuring 3.5 cm. in length and 2.5 cm. in diameter in the ileum approximately 3 cm. from the ileocecal junction. The diverticulum was ruptured and the gap covered over by thickened peritoneum, which itself was the site of a marked inflammatory reaction and had a thick greenish-brown fibrinopurulent exudate on its surface. The walls of the diverticulum were thin, necrotic and also covered with this patchy exudate. The cut surface of the intestine revealed a hemorrhagic, necrotic wall. The mucosa in the diverticulum was largely sloughed. A review of the world literature disclosed no similar case.

Radioactive Gold in Treatment of Carcinoma of Prostate.—Older methods of irradiation proved unsatisfactory in cancer of the prostate, because, although sufficient radiation could be applied to destroy the tumor, adjacent normal structures, notably the rectum and bladder, received too much radiation. With the advent of Au^{198}, whose main radiation component is beta rays, the prostate seemed a site in which to try this isotope. The first patient was a 72-year-old man who had had a transurethral resection for obstruction, and had been treated with diethylstilbestrol for the five months after it had been demonstrated that cancer of the prostate was present. Radioactive gold was used, and in three weeks the large, hard mass was impalpable. Ninety-two days after the injection, biopsy specimens were negative for carcinoma. In the past 17 months, the authors treated 120 cases of inoperable carcinoma of the prostate with radioactive gold. All possible operative procedures are carried out before the injection of the gold is begun. After estimation of the amount of tissue involved by malignancy, the radiologist measures the amount of radioactivity desired and dilutes it to the proper volume. He then loads the protected syringe and passes it to the urologist who does the injecting. Usually from 8 to 16 cc. of the diluted material of Au^{198} are injected into the prostate from within the bladder. The periprostatic region and the seminal vesicles are injected transvesically and extravesically. Palpable nodes are also injected. If the estimated amount of involved tissue was between 20 and 35 gm., the authors used 3 mc. per gram; if 35 to 70 gm., 2 mc. per gram; if 75 to 150 gm., 1 mc. per gram of tissue. Because of complications, this dosage schedule was later reduced to 1 mc. per gram; but the regression of the tumors so treated has not been as satisfactory as with the earlier dose. At the present the authors feel that a moderate sized prostate, between 30 and 60 gm., is probably best treated with a millicurie per gram ratio of 2 to 1. About 98% of the patients treated showed rapid decrease in the size of the palpable neoplasm. Eleven of 37 cases with postinjection biopsies showed no evidence of neoplasm. Of the 50 patients observed from 6 to 17 months, 27 are alive without evidence of clinical disease and seven died without evidence of carcinoma. Eight are alive with clinical disease and eight died with the disease. Complications are almost exclusively confined to rectal irritation. There were 15 cases in the first 50 and three in the subsequent 67 with this complication. Four developed rectal ulcers, three of which required colostomy.

Action of Streptomycin and Isoniazid Singly and in Combination.—Hobby and associates present the following results of in vitro and in vivo studies that indicate the high degree of antituberculous activity of isoniazid against both streptomycin-susceptible and streptomycin-resistant organisms. The emergence of resistance to combinations of streptomycin and isoniazid occurs more slowly than to either compound alone. Neither compound is capable of preventing the ultimate emergence of resistance to the other. Cross-resistance between streptomycin and isoniazid may occur under certain conditions despite the fact that isoniazid is effective against streptomycin-resistant organisms not previously in contact with isoniazid and that streptomycin is effective against isoniazid-resistant organisms not previously in contact with streptomycin. It was concluded, therefore, that streptomycin and isoniazid, when used under appropriate conditions and in adequate quantities, may act synergistically both in vitro and in vivo. Not enough data are available to permit the assumption that the impressions gained from the observations reported would apply to all strains of Mycobacterium tuberculosis. There is some evidence that the action of isoniazid alone and in combination with streptomycin against Myco. butyricum may differ from its action against the H37Rv strain of Myco. tuberculosis. Further evidence is needed to confirm this impression and to prove whether or not all strains of Myco. tuberculosis var. hominis parallel the strains used in the present study.

Caseation Necrosis in Human Brucellosis.—A 21-year-old man was hospitalized on May 23, 1951, with the chief complaints of vomiting and diarrhea. He had been in good health until May 21, 1951. He was aware of an asymptomatic generalized lymphadenopathy for several weeks prior to this illness. For almost a year preceding the illness he had been employed in a meat-packing plant where he slaughtered cattle and hogs. Some three months before this hospitalization, he sustained a laceration of his lower lip when struck by the thrashings of a pig. This lesion healed. His temperature now was 102.2 F, and he was acutely ill. Several nontender firm cervical lymph nodes, 0.5 to 2 cm. in size, were palpable. Similar lymph nodes could be felt in the supraclavicular, axillary, inguinal, and epitrochlear regions. Brucella suis recovered by blood cultures was highly susceptible in vitro to chloramphenicol, aureomycin, and streptomycin and was resistant to penicillin and sulfadiazine. A supraclavicular lymph node was biopsied on June 1, 1951, and on pathological examination it was found to consist of five firm, gray-white lymph nodes with yellow, granular cut surfaces. Microscopically, the lymph nodes were poorly circumscribed and partially encapsulated. Almost the entire section was composed of large confluent masses of avascular caseation necrosis. Scattered foci of calcification were noted. Because of the clinical evidence of toxicity and abnormal urine findings, the patient was given 1.5 gm. of aureomycin daily for 12 days, or a total of 18 gm. There was prompt clinical improvement characterized by subsidence of fever, malaise, nausea, vomiting, diarrhea, and abdominal distress. The lymphadenopathy noticeably regressed. The Brucella agglutination titer gradually rose, and blood cultures five weeks after the onset of the acute illness yielded the growth of Brucella suis. A second course of aureomycin was instituted consisting of 0.5 gm. every six hours for 14 days, or a total of 28 gm. Blood cultures became negative following this therapy, and there was a gradual fall of the agglutination titer. The patient regained 10 lb. (4.5 kg.) in weight. On discharge, he was asymptomatic and afebrile, but two blood cultures after return from a convalescent furlough were positive for Brucella suis, and so the patient was recalled for further therapy. A review of the literature of pathological material from the Armed Forces Institute of Pathology indicates that the inflammatory reaction to the Brucella organism is, in general, nonspecific.

*Herniation of Lumbar Intervertebral Disks in Coal Miners: Preliminary Report. E L. Gage and W. A. Shafer.—p. 577.

Herniation of Lumbar Intervertebral Disks.—Gage and Shafer have operated since 1946 on 564 patients for herniation of intervertebral disks. The report deals with 303 of these patients, who were coal miners. Some of these men worked at loading coal while on their knees or in a stooped position in coal tunnels no higher than 26 to 40 in. (65 to 100 cm.). Direct injury was claimed by 35.9% as a cause of their complaints but in only 22.7% was a connection with work injuries accepted. A rather high percentage of the miners (nearly two-thirds) had multiple disk involvement. This may be due to the fact that many with single disk lesions may have become symptom-free with conservative treatment. No disk lesion was found in 3.6% at operation. Plain roentgenograms and laboratory tests were not sufficient for diagnosis, which was made primarily by a neurological examination supplemented in 14% of the cases by myelography. At the last follow-up 277 of the miners either returned to work or were convalescing satisfactorily. Their ability to remain at work must be determined by a five year follow-up study. The authors believe that miners with true disk herniation who have not been relieved by conservative treatment should be operated upon and that the majority of these patients can then return to work at the mines. Most miners who have had multiple disk lesions should not work in extremely low coal seams, however.

Anemia in Rheumatoid Arthritis.—Moderate anemia is a common feature of rheumatoid disease but its origins remain obscure and its treatment is frequently unsatisfactory. The presence of anemia may hinder adequate physical or orthopedic treatment and may produce a degree of lassitude that considerably aggravates the joint disability. Investigations on the following aspects of this anemia are reported: (1) changes in the peripheral blood and bone marrow, (2) blood, plasma, and corpuscle volumes, and (3) changes in iron metabolism. The patients studied had active rheumatoid arthritis, uncomplicated by any disease liable to affect hemopoiesis. The patients were partly "selected" by the fact that this hospital receives a predominance of cases refractory to outpatient treatment, such as gold or simple physiotherapy. The series included patients of various ages, differing widely in the severity and duration of their disease, and is believed to represent a fair sample of cases of active rheumatoid arthritis associated with anemia. The anemia was essentially normocytic and hypochromic, the mean corpuscular volume being usually normal and the mean corpuscular hemoglobin content and concentration usually reduced. Anemia was more pronounced in the presence of very active disease. The myelogram suggested impaired maturation of normoblasts and retarded hemoglobin formation. The blood and plasma volumes were not essentially abnormal, though the frequent asthenic habitus and loss of weight might produce apparently exalted values in terms of body weight. Changes common to many anemias were found in the relatively severe cases of anemia, that is, normal plasma volume with decreased corpuscle and whole blood volume. The plasma iron concentration was usually reduced; subnormal values were invariable in cases with very active disease or marked anemia. The iron-binding capacity of the serum might be raised by iron deficiency or slightly reduced but not enough to be a factor in producing or maintaining anemia. As judged by changes in the plasma iron, intestinal absorption of iron after a single maximal therapeutic dose was variable. Some cases showed the excellent absorption and therapeutic response characteristic of simple iron deficiency. Others gave evidence of impaired absorption.

Platelet Transfusion in Postirradiation Hemorrhagic State.—The hemorrhagic state following massive irradiation is characterized by the appearance of erythrocytes in large numbers in the lymph. The peak of this erythrocyte diversion into the lymph is reached in rats at 9 to 14 days and in dogs at 11 to 17 days after irradiation. The parallel between the postirradiation hemorrhagic tendency and the decrease in circulating platelets has been confirmed by several workers. A new impetus to studies of the role of platelet deficiency in radiation injury was given by the work of Cronkite and coworkers, who demonstrated that daily injections of platelet suspensions begun before thrombocytopenia developed prevented the hemorrhagic phase. This study describes the extent to which platelet injections diminish the hemorrhagic tendency of irradiated dogs and rats as indicated by erythrocyte counts in the lymph. Suspensions of concentrated, homologous blood platelets when introduced intravenously into lymph-cannulated dogs and rats (9 to 12 days after exposure to an LD$_{50}$ or greater dose of x-rays) eliminated the large scale diversion of erythrocytes into the lymph during the hemorrhagic phase of radiation injury. By means of injection of platelets preinjection levels of below 50,000 were raised to an average of 107,000 in 6 dogs, and to an average of 310,000 in five rats at 15 to 30 minutes after injection. All platelet-injected animals showed clearing of the bloody lymph within the first hour after injection, and within five to six hours the average erythrocyte count in the lymph of dogs dropped from an average of 270,000 to an average of 12,000 and in the rats from an average of 900,000 to an average of 30,000. No depression of lymph erythrocyte counts was found in control rats receiving plasma only. Lymph erythrocyte counts in the platelet recipients remained low for 24 to 36 hours after injection; bleeding into the lymph space reappeared in both rats and dogs when the platelet level dropped below approximately 50,000. Blood platelet and lymph erythrocyte levels are excellent indexes of the severity of the hemorrhagic phase of radiation injury and for gaging the results of therapeutic procedures. While the mechanism of platelet action remains to be demonstrated, the present studies support the thesis of earlier workers that platelets are essential to maintain vascular integrity and that a platelet deficiency is the main cause of the postirradiation hemorrhagic state.

Roentgenographic Demonstration of Pneumoperitoneum in Perforated Peptic Ulcer.—The proved cases of perforated ulceration of the stomach and duodenum observed at the San Francisco City and County Hospital in the eight year period ended July 1, 1950, were reviewed. All cases in which there was a final diagnosis of perforation of benign ulceration were included, whether or not the perforation was sealed off or adherent to the liver or the pancreas at the time of operation or autopsy. The total was 337 cases. Roentgenologic examination was performed in 324 cases. A review of the data on these 324 cases indicated that pneumoperitoneum is more likely to be demonstrated in roentgen films made within six hours after perforation than in films made after a longer interval. In several cases films made early did not show intraperitoneal gas and later films did. There appeared to be no constant relationship between the size of the perforation and the incidence of demonstrable pneumoperitoneum; it was less often demonstrated in cases of posterior perforation than when the lesion was at an anterior site. In many cases roentgen examination was performed with the patient in both the erect and the left lateral decubitus positions. These two roentgenographic views were equally reliable, and there was agreement between them in 94% of the cases. Clinical factors may influence the decision as to which position should be used. It is easier for a patient with acute pain in the abdomen to turn on his side than to sit erect. Also, the lateral decubitus position may facilitate the escape of intraluminal gas if there is considerable fluid in the stomach. If the physical condition of the patient permits, it would seem wise to take films in both positions.

Blood-Borne Tumor Metastases.—This paper reviews concepts of the mechanisms of metastasis in the light of knowledge gained from experiments during the past 10 or more years. The local invasiveness of cancer cells is primarily dependent upon loss of the mutual adhesiveness of the cells, which loss is associated with, if not due to, local calcium deficiency. The easily detached single cancer cells, or small clusters of them, are ameboid and are thereby enabled to penetrate the adjacent tissues. Distant dissemination of cancer cells is largely dependent upon entrance of cells into vascular channels through which they are carried to other parts of the body. Duration of growth of the primary tumor bears a positive relationship to the number of metastases, whereas the size of the primary tumor is less effective in influencing the number of metastases. The venous distribution of metastases is largely dependent upon the anatomical arrangement of the venous channels (including the vertebral veins) into which emboli are commonly released. This accounts for the frequency of metastatic involvement of the lungs, the liver, and the bones of the spine, pelvis, and skull. The arterial distribution of metastases is also dependent upon the number of embolic cells reaching the various organs, and in addition depends upon whether the embolic cancer cells lodge in capillaries and sinusoids or in thick-walled arterioles. These phenomena are variable from organ to organ, and may account for the relative infrequency of metastasis to some organs (spleen, muscle) and the frequency of metastasis to other organs (adrenals, kidney). The lungs, although frequently the site of metastatic tumors, apparently afford relatively adverse conditions for tumor growth. This may be attributable to the peculiar physical structure. Single embolic cells or tiny clusters, rather than large clumps, give rise to most metastases, because these cells are able to reach the capillary bed whereas large clumps lodge in arterioles. "Soil" factors affecting the distribution of metastases seem to consist chiefly of physical or mechanical circulatory differences rather than of chemically favorable or unfavorable environments for the growth of tumor cells.

Hypercalcemia, a Complication of Hormone Therapy in Breast Cancer.—Kennedy and associates call attention to the fact that hypercalcemia is a potential serious complication during androgenic and estrogenic hormone therapy of patients with advanced breast cancer. Nine patients with obvious hypercalcemia were culled from a series of 361 women with advanced cancer of the breast who were treated with sex steroid hormones. The complication occurred only in patients with osseous involvement. Eighty-four of 253 patients treated with estrogens and 97 of 108 treated with androgenic hormones demonstrated osseous metastases. Of these, seven patients treated with androgens and two patients treated with estrogens developed manifestations of the hypercalcemia syndrome. Two patients with hypercalcemia, not included in the above consecutive series, were studied recently and have been incorporated in this report. The case histories of the 11 patients are presented. Metabolic studies of patients with "induced hypercalcemia" demonstrated an elevated serum calcium, hypercalcuria, altered serum and urinary phosphorus levels and occasionally renal insufficiency. Immobilization, possible acceleration of tumor growth, and removal of barriers to the spread of cancer cells may contribute to the development of the hypercalcemia. The resemblance to the metabolic effects of parathyroid hormone is described in one case. The occurrence of hypercalcemia as a complication of hormone therapy of breast cancer does not contraindicate its general use. Nor does the presence of a spontaneous elevation of serum calcium preclude hormone therapy. Once hypercalcemia is manifest, discontinuance of the hormone may be followed by a decrease of the serum calcium. Parenteral administration of fluid to prevent severe dehydration and measures to correct the electrolyte imbalances are helpful. A low calcium diet aids the reduction of the serum calcium. Sodium citrate may be given to reduce temporarily the amount of ionized calcium in the blood by formation of a soluble, nonionized calcium citrate complex. Caution must be exercised in regard to the total amount of sodium citrate given in a day, because if the renal function is impaired, alkalosis may be produced.

Cell Types in Bronchogenic Carcinoma.—The records of 1,000 patients with proved carcinoma of lung, taken at random from the files of the Mayo Clinic, were reviewed. Of the 895 men and 105 women between the ages of 22 and 80 years, 90 had small cell carcinoma, 137 had adenocarcinoma, 378 had large cell carcinoma, and 395 had squamous cell carcinoma. The ratio of men to women was 29:1 with small cell carcinoma and 25.3:1 with squamous cell carcinoma. The difference in the ratio of men to women was not so great in the two other cell types, being 3.4:1 for adenocarcinoma and slightly less than 6:1 for large cell carcinoma. The average age of the patients was slightly lower in those with small cell carcinoma than in patients with the other types of tumor. The duration of symptoms was shorter in patients with small cell carcinoma than in those with other types of tumor. In all of the cases of small cell carcinoma the patients had symptoms referable to the thorax. Such symptoms were not present in all of the patients with other types of carcinoma. With the exceptions noted, the symptoms were essentially the same in all patients. Roentgenographic examination of the thorax disclosed an abnormality in all but 12 of the total of 1,000 patients. Bronchoscopy was not performed in all patients in the respective groups. It was a very effective diagnostic procedure in those in whom the tumor arose from the central portion of the lung, that is, in cases of small cell carcinoma and in cases of squamous cell carcinoma. Cytological examination of the sputum or bronchial secretions was more effective in patients with small cell carcinoma and least effective in those with adenocarcinoma. The results of surgical treatment were more satisfactory in patients with squamous cell carcinoma than in those with other types of carcinoma. The results of surgical treatment were least satisfactory in patients with small cell carcinoma.

Pulmonary "Coin" Lesions.—Pulmonary "coin" lesions, as defined by Davis and Klepser, are located in the lung substance, and are round, oval or lobulated, with their edges sharply demarcated and contours smooth, without cavitation and usually without calcification. In this type of lesion, a definitive diagnosis usually cannot be confirmed by the various laboratory and x-ray procedures. The diagnosis requires surgical exploration for the removal of the nodule and pathological study. When this is done, these lesions, many of which look similar on the x-ray film, will finally be diagnosed as a large variety of pathological entities. The author presents five illustrative cases in three men and two women between the ages of 34 and 72. Exploratory thoracotomy was performed in all five patients, and the mass was removed. The pathological diagnoses were chronic granuloma (probably due to histoplasmosis), Boeck's sarcoid, tuberculoma, bronchial adenoma, and squamous cell carcinoma of the lung. The important fact is that in various series reported in the literature, from 15 to 30% of the lesions were malignant, and in some specially selected older age groups as high as 70%. Small flecks of calcium, not clearly part of a Ghon complex, do not rule out the possibility that the lesion may be malignant, and they are not a contraindication to exploratory procedures. Exploratory thoracotomy is a benign procedure comparable in risk to appendectomy and should be thought of in the same way as most physicians and even the general public have been educated to think about biopsy of a lump in the breast. The nodule should be removed so that a definite pathological diagnosis can be made. It should not just be watched until a clinical diagnosis can be achieved because by that time metastases are likely to be present and the chance for successful surgery has been greatly reduced. Agreement on these points is almost universal among men skilled in treating diseases of the chest, but is not as widespread among the general medical profession and certainly not among the general public.

Kartagener's Syndrome in Children.—The occurrence of Kartagener's syndrome in four girls and one boy between the ages of 6 weeks and 14 years is reported. Of the five children with transposition of the heart to the right side four had complete situs inversus and one had dextrocardia only. Atelectasis, early or late bronchiectatic changes, and sinusitis were present in all patients. Lobectomy was performed on three with beneficial results. The youngest patient died before the operation could be performed. The author believes that some congenital factor plays a part in the pulmonary features of the disease. It has not been established whether there is a developmental error in the bronchial walls or whether the pulmonary lesions are secondary to the cardiovascular anomalies. It is probable that in most instances atelectasis precedes bronchiectasis. The treatment of Kartagener's syndrome consists of resection of the affected pulmonary tissue as soon as the patient is deemed a good surgical risk. The age of the patient in the younger years, after the neonatal period, need not be considered in making the decision. Treatment of sinusitis is indicated, although it is usually not nearly so successful as that of the bronchiectasis.

Perirenal Oxygen Insufflation.—Ritter and Johnson point out that the introduction of gases into the perirenal area was first advocated by Carelli. In their own studies they combined Carelli's technique with that more recently described by Rivas. The purpose of the perirenal insufflation is to visualize the structures of the retroperitoneal areas, particularly those lying immediately below the diaphragm. They believe that it is incorrect to say that the Carelli or the direct method of perirenal insufflation is now replaced by the Rivas or the indirect method. These two methods are interrelated; one complements the other. They have found that in cases in which the technique of Rivas failed to reveal the structures of the perirenal area, resort to the Carelli method clearly outlined a tumor of the kidney. Perinephritis and perirenal extravasation due to trauma can be ruled out, when oxygen reaches the renal areas and surrounds the kidney. After experimenting with several gases, the authors found oxygen the most satisfactory and the least dangerous. They describe a new apparatus for accurate measurement of the quantity of gas injected and for recording the pressure under which the gas is introduced. Perirenal insufflation represents a valuable addition to the urologic diagnostic armamentarium.

Surgical Treatment of Mediastinal Lymphoblastoma.—The 10-year-old boy whose history is given had been well until two weeks prior to entrance into the hospital. At that time he complained of pain and "fullness" over the right side of the chest. This was especially marked whenever he attempted to run. Physical examination revealed a slight bulging and diminished breath sounds over the anterior aspect of the right side of the chest. The roentgenogram revealed a mass located in the anterior and middle mediastina. The barium-filled esophagus showed the close proximity of the tumor. The impression was that there was either a dermoid or a teratoma in the anterior mediastinum. The tumor was found to compress the lung, extending from the apex to the right and left innominate veins superiorly, to the pericardium medially and to the superior vena cava posteriorly. Frozen section revealed a lymphoblastoma. It was possible to enucleate the entire mass. The chest was closed and water seal drainage instituted. The postoperative course was uneventful, and a postoperative roentgenogram on the second day revealed good expansion of the right lung. One year has passed since the operation, during which time the boy has been given irradiation therapy. The boy's condition was good at the time of writing this report. In a review of literature 12 similar cases were found in which the patients were operated upon with apparent complete removal of a solitary mediastinal lymphoblastoma. Time and additional experience will be needed to determine whether or not surgical removal of such solitary lesions prior to irradiation will favorably alter the course of this disease.

Serum Levels Following Penicillin Administration.—Penicillin levels in the serum of normal premature infants, normal full-term newborn infants, older infants from 2 weeks to 2 years of age, and children from 2 to 13 years of age were obtained after the administration of the following preparations of penicillin: (1) unbuffered oral potassium penicillin G, administered in a flavored vehicle containing 100,000 units per 5 cc.; (2) oral procaine penicillin administered in a flavored vehicle containing 250,000 units per 5 cc.; (3) crystalline potassium penicillin G diluted with sterile distilled water to a concentration of 100,000 units per cubic centimeter and administered by intramuscular injection; and (4) procaine penicillin diluted with sterile distilled water to a concentration of 300,000 units per cubic centimeter and administered by intramuscular injection. The various penicillin preparations were given in single doses of 10,000 units per pound of body weight. The penicillin assays were determined by a modification of Rammelkamp's serial dilution method. The test organism was group A hemolytic Streptococcus C-203. Distinctly higher and more sustained blood levels were observed in the full-term newborn and premature infants than in older infants and children after the administration of comparable doses of all four preparations. Lower gastric acidity and inefficient renal function in newborn infants may explain the differences observed between the newborn and older age groups. Minor differences have been observed in the levels following the administration of orally administered potassium penicillin G and orally administered procaine penicillin. Orally administered penicillin in doses of 10,000 units per pound of body weight produced levels of at least 0.03 unit per cubic centimeter for a minimum of six hours in full-term newborn and premature infants, for a minimum of four hours in infants up to 2 years of age, and for at least two hours in children over 2 years old. In all groups, intramuscularly administered potassium penicillin G in doses of 10,000 units per pound of body weight resulted in very high initial levels. The levels declined rapidly, however, so that the six hour levels were comparable to those observed after the oral administration of penicillin in all age groups except the youngest newborn infants. Intramuscularly administered procaine penicillin in doses of 10,000 units per pound of body weight produced high sustained levels for six hours; detectable levels were often demonstrable at the end of 24 hours. The ease with which therapeutically effective levels of penicillin can be achieved in the serum by the oral administration of penicillin indicates definite usefulness of this route of administration in the treatment of infections caused by penicillin-susceptible organisms in newborn and premature infants. A dose of 10,000 units per pound of body weight administered every 12 hours, or 20,000 units per pound of body weight per day, should be effective in the treatment of such infections in full-term newborn and premature infants, while an oral dose of 10,000 units per pound of body weight given at six hour intervals should be adequate for older infants and children. The dosage schedule of parenterally administered penicillin should be guided by the susceptibility of the organism. Beyond early infancy, the doses for infants and children should be comparable as based on body weight.

Erythromycin in Treatment of Pyoderma.—Ten children between the ages of 18 months and 12 years with impetigo and secondary pyoderma were treated with erythromycin ointment (Ilotycin). The ointment was applied locally over the affected areas in all patients. Four patients received erythromycin orally along with the local therapy. In all patients no new lesions appeared after 24 hours of treatment, and crust formation and healing were usually evident in 48 to 60 hours. The average patient received treatment for five days. The healing process continued after the treatment was discontinued. No recurrence developed. Transient hyperpigmentation occurred after healing in most patients. There was no evidence of drug sensitization or other untoward reactions. The courses of the four patients who received oral as well as local treatment with erythromycin were not pronouncedly different from those receiving local therapy alone. The authors feel that erythromycin ointment will prove of value in treating superficial skin infections caused by gram-positive bacteria.

Methantheline in Infantile Pylorospasm.—Eight infants with pylorospasm and one infant with cardiospasm, diagnosed clinically and confirmed by x-ray, were treated with methantheline (Banthine) bromide. The infants with pylorospasm were given 5 mg. of the drug, four times a day, while the one infant with cardiospasm required 50 mg. daily. The usual course of treatment was of one month's duration. All patients that were studied with post-treatment gastrointestinal x-ray series showed demonstrable roentgenographic improvement. Clinically, all eight infants with pylorospasm responded dramatically to methantheline treatment with cessation of vomiting. The infant with cardiospasm and a history of almost daily episodes of forceful vomiting immediately after feeding received methantheline for over two months and had a good clinical result. No toxic effects from the use of the drug were observed. Methantheline bromide is a useful adjuvant to the therapy of infantile pylorospasm.

Infectious Hepatitis in Childhood.—The occurrence of infectious hepatitis is reported in 40 children up to 15 years of age in Denver between 1946 and 1951. There were two deaths of the fulminant type after a total course of nine and eight days respectively in a 5-year-old boy and a 2-year-old girl. Necropsy was performed in both cases, and the liver showed the typical microscopic picture described by Lucké and Mallory. A third death occurred in a 10-year-old boy two months after the appearance of the first symptoms of infectious hepatitis. This patient had a syndrome that was unrelenting from the initial attack and included signs of portal hypertension with ascites, edema, jaundice, and fever. He died a few days after a surgical attempt to ligate his hepatic artery when the ascites had become uncontrollable. The postmortem examination of the liver revealed "subacute necrosis and regeneration," characterized by distortion of the lobular architecture by fibrosis, nodular regeneration of liver cells, and leukocytic infiltration. The 37 remaining patients were considered to have recovered completely from the acute disease. The usual illness began with fever and signs of upper respiratory infection, followed in one to two days by gastrointestinal complaints, including anorexia, nausea, and vomiting. Approximately 12 hours later abdominal pain began. On the fourth or fifth day dark urine or light-colored stools were noted. On the fifth or sixth day jaundice became apparent. Temperature usually was restored to normal with the onset of jaundice. Coupled with this typical clinical story, the laboratory findings of bile in the urine in a high percentage of the patients, an elevated serum bilirubin in all of the patients, an erythrocyte sedimentation rate that was elevated almost without exception, and a normal white blood cell count with a normal differential count confirmed the diagnosis of acute infectious hepatitis in childhood with few exceptions. Jaundice was observed in all of the authors' patients except one, who had the fulminant type and died on the eighth day. The authors believe that there are three clearly defined courses that a case of acute infectious hepatitis may pursue. The first and commonest is the "benign course"; the second, and most disastrous, is "fulminant hepatitis"; and the third, for which the term "progressive hepatitis" is proposed, is the syndrome already described by Alsted, Jersild, Wyllie and Edmunds, that may either end fatally in two to nine months without remission from the initial attack of hepatitis, or may result in at least an apparent clinical cure after this "progressive" period. The authors were unable to find in the American literature reports of cases similar to that of progressive hepatitis with fatal termination in their 10-year-old patient. They agree with Wyllie and Edmunds that the development of signs and symptoms of portal hypertension following an attack of infectious hepatitis in weeks or months is of grave prognostic significance.

Benign Tumors and Cysts of Esophagus.—Most of the data reviewed in this paper were collected from the reports of 163 cases of tumors and cysts. Some were clinically manifest, and others were incidental autopsy findings. Forty other cases were reviewed and discarded because of incomplete clinical or pathological information. The clinical material includes 40 intraluminal polypoid tumors, 46 solid intramural tumors, and 17 cysts. The sessile intraluminal growths, supernumerary tissues, muscular hypertrophy, and inflammatory conditions are discussed in the section on pathology, since many did not produce symptoms. Benign tumors of the esophagus may be divided into two groups: the intraluminal and the intramural. In the former group most of the tumors are fibrous polyps, although polypoid lipomas and leiomyomas occur. The majority of these intraluminal tumors are attached in the region of the cricoid cartilage. Sessile intraluminal growths occur, but rarely, if ever, are of clinical importance. The solid intramural tumors are predominantly leiomyomas and may be found at any level. The intramural cysts are congenital in origin and usually contain derivatives of the primitive foregut. Most of these occur in the middle or lower thirds of the esophagus. Supernumerary tissues, other than gastric epithelium, rarely appear in the esophagus and inflammatory conditions are not common. The tumors, particularly the polyps, may be difficult to diagnose, but roentgenography and esophagoscopy are helpful. Most of the polypoid tumors may be removed via the esophageal lumen, whereas a thoracic or abdominal approach plus enucleation and/or resection is necessary to treat the intramural growths. Malignant polypoid and intramural tumors occur that clinically can mimic the benign growths. A good prognosis may be expected provided an accurate diagnosis is made and proper therapy is employed.

Surgical Correction of Atrial Septal Defects.—Among their patients with atrial septal defects, Neptune and associates observed five with anomalous drainage of the veins of the right lung into the right atrium, just to the right of the remnant of the atrial septum. None of these defects were of the persistent ostium primum type; all were located posteriorly in the septum, although they varied in their distance from the auriculoventricular valves. They were relatively large, even in the children, and capable of admitting one to three fingers. Among the various methods that have been tried or suggested for the closure of atrial septal defects, Bailey's atrioseptopexy technique was the first effecting complete surgical closure of large defects of this type. Neptune and his associates used successfully a simple modification of this atrioseptopexy technique in two of five cases that were observed since this technique was developed. Detailed case reports of these two patients with septal defects and transposition of the pulmonary veins of the right lung are described. Successful repair of the defects was proved by cardiac catheterization. The technique for the complete surgical correction of atrial septal defect associated with transposition of the pulmonary veins of an entire lung is presented. A method for correction of anomalous pulmonary venous drainage of all pulmonary veins into the right atrium and/or its tributaries is suggested.

Amniotic Fluid Pulmonary Embolism.—Pulmonary embolism caused by amniotic fluid is a rare entity, only 44 cases having been reported since it was first described by Steiner and Lushbaugh in 1941. The condition is characterized clinically by sudden shock during labor in a previously asymptomatic woman. Its cause may be strong or tetanoid contractions, administration of pitocin, quinine or castor oil, an oversize fetus, prolonged intervals between deliveries, multiparity, previous cervical laceration and conization, and sometimes obstetric abnormalities. Diagnosis is based on the clinical picture; autopsy may reveal a ruptured uterus, pulmonary edema, edema and hemorrhages in the broad ligament, retroperitoneal hematoma and hemorrhage, and embolism. Histological examination may show amniotic fluid elements, such as epithelial squamae, meconium, vernix caseosa, mucinous debris, and lanugo in the pulmonary vessels. Although death has been ascribed to reflex vasospasm or mechanical occlusion and anoxia, anaphylaxis seems to be the most likely cause. Late studies have revealed that normally the amniotic fluid passes through the placental barrier, enters the maternal circulation, and is excreted through the kidneys. Thus, primary sensitization of the mother to the amniotic fluid is explained, and, when the amniotic fluid enters suddenly into her blood stream during the shock, anaphylaxis ensues. The authors report two cases of amniotic fluid pulmonary embolism in a total of 26,322 deliveries at the obstetrical department of St. Anthony's Hospital in St. Louis during the last 10 years. The diagnosis was established in both patients on the basis of the clinical picture. In the first patient, a 35-year-old woman, para 5, with a previous cervical conization, a ruptured uterus and amniotic fluid extravasation were found at autopsy; histological examination of the lungs revealed amniotic fluid particulates in the pulmonary vessels. In the second patient, a 41-year-old woman, para 7, microscopic examination did not show amniotic fluid constituents in the lungs but autopsy revealed emboli in the bifurcation of the pulmonary artery and extravasation of amniotic fluid in the left pelvic floor adjacent to an area of uterine softening that possibly may have been a uterine tear.

Cortisone in Nodular Nonsuppurative Panniculitis.—Results are reported of cortisone therapy in two women with nodular nonsuppurative panniculitis. The disease in both patients was confined to the lower legs, although as a rule the subcutaneous tissues of other parts of the body are also involved. Both legs were greatly swollen in the first patient, and tender nodular swellings were present beneath the skin in the calves. Despite administration of antibiotics and sulfadiazine, the number of nodules continued to increase and the pain increased to such an extent that the patient was confined to a wheel chair. Cortisone therapy was then attempted; a dose of 50 mg. was given at first four times daily, then, after the first improvement, three times daily, and finally twice daily. Within two weeks the swelling had disappeared from both legs, and only one or two small but not tender nodules were still present in each calf. The patient was discharged and continued to take the drug for four weeks. After four months she was still well and was doing her own housework. A relapse occurred six months after she left the hospital, but the recurrent symptoms subsided again with cortisone therapy. Administration of 50 mg. of the drug four times daily for 10 days brought about a prompt improvement in the other patient. Four months later she was well and only small depressions over the posterior surface of each calf could be seen. Cortisone is valuable in the treatment of nodular nonsuppurative panniculitis but it is not a cure. The cause of this disease is still unknown. Observations in these two cases suggest that it probably is not a local bacterial infection and that the tissue reactions that cause the onset of the symptoms are suppressed by cortisone in the same manner that this drug suppresses the tissue reactions in some collagen diseases. A relationship to collagen diseases is suggested by the similar response to cortisone therapy and the relapsing course of nodular nonsuppurative panniculitis, but further evaluation of cortisone therapy in this disease is needed.

Multiple Myelomas Occurring in the Jaws.—The case records and roentgenograms of the jaws of 59 patients with myeloma were reviewed. Of these patients, 17 exhibited evidence of myeloma in the jaws. Whereas the ratio of males to females was approximately 2 to 1 in the 59 patients, among the patients with lesions in the jaws women predominated. All but one patient with myeloma of the jaws had general skeletal involvement; this patient had a solitary myeloma of the jaw and no lesions elsewhere in the skeleton. The mandible was more frequently involved than the maxilla. Lesions occurred oftener in the posterior portion of the body, the angle, and the ascending ramus of the mandible than elsewhere in the jaw. More patients exhibited lesions in the skull than in the jaws. Symptoms referable to the jaw, such as pain, pressure sensation, numbness, swelling, expansion of the jaw, mobility of teeth, and epulis formation, were observed. In seven cases the initial symptoms of myeloma were observed first in the jaw. Usually myelomas of the jaw appear roentgenographically as multiple rounded lesions that have little circumferential osteosclerotic bone reaction. These vacuolated configurations are frequently situated within a larger region of diffuse radiolucency with hazy ill-defined margins. Histopathologic examination of tissue from the jaw in 5 cases disclosed tumor tissue that was composed of closely packed anaplastic cells resembling plasma cells. The supporting stroma was scanty but vascularity was prominent. This study demonstrates the prevalence of myelomas in the jaw and illustrates that oral examination can be helpful in the diagnosis of generalized disease.

Osteogenesis Imperfecta with Dentinogenesis Imperfecta.—Osteogenesis imperfecta, osteopsathyrosis, fragilitas ossium, blue sclera and brittle bones are synonymous. Dentinogenesis imperfecta, odontogenesis imperfecta, and hereditary opalescent dentine are synonyms of allied dental disturbance, which is characterized by chipping and cracking of the enamel with a rapid wearing down of the teeth, and an opalescent color described as blue, gray, and reddish-brown. The case presented is one of osteogenesis imperfecta tarda illustrating the typical physiognomy, history, and allied dental disturbance. The patient was a 17-year-old youth, who complained that the enamel of his teeth was chipping off. The teeth were opalescent gray-brown. The physiognomy was characterized by bitemporal protuberances with the ears turned out and forward. The forehead appeared broad, but the maxilla and mandible appeared small. This gave a triangular shape to the face. When questioned regarding the history of fractures, the patient admitted having suffered fractures of the left clavicle five times, of the left humerus once, and of the little finger on the left hand once.

Isoniazid in Pulmonary Excision for Tuberculosis.—Preliminary observations are presented on the use of isoniazid and iproniazid in excisional surgery of the tuberculous lung and in the treatment of complications of resection. Twelve patients received the isoniazid preoperatively, and a second group of 28 patients received it only for postoperative complications. The authors gained the impression that, with the use of the isonicotinic acid derivatives, lung resection may be made available to more patients with far advanced pulmonary tuberculosis than was hitherto considered possible. Operation may be done for lesions that would ordinarily be considered inoperable. Complications that follow resection may be managed better with the aid of these drugs.

Advantages of X-Ray Diagnosis in Pregnancy.—Barter and Parks believe that even though x-ray diagnosis is being used oftener in obstetrics, relatively few obstetricians utilize its full potentialities. Discussing roentgenologic pelvimetry, the authors say that, while ideally all primigravidas should be subjected to x-ray pelvimetry, as a rule it is done only for those in whom abnormalities are revealed by manual mensuration. Such abnormalities include a diagonal conjugate of 11.5 cm. or less, a reduction in the interspinous and intertuberous diameters, abnormal curvature or forward displacement of the sacrum, and the characteristics of the masculine type of pelvis. Roentgen ray pelvimetry is indicated also in primigravidas with a breech or other abnormal presentation or with an unengaged fetal head at term. Roentgen ray pelvimetry is indicated in all pregnant women who are less than 5 ft. (152 cm.) tall, who have an abnormal presentation, particularly if the fetus seems larger than previous ones, who have a history of difficult labor or of previous cesarean operation, whose labors are progressing poorly, or who have a history of a pelvic fracture. The presence of true uterine inertia should never be accepted unless cephalopelvic disproportion has been ruled out as a cause of ineffective labor. Aside from pelvimetry, roentgen examination is helpful in determining the presentation and position of the fetus and in the diagnosis of multiple pregnancy. In the presence of an overdistended uterus, roentgen examination is important to differentiate between polyhydramnios, a single large fetus, or a multiple gestation. In the late weeks of pregnancy the age of the fetus may be determined to some degree. Antepartum diagnosis of an anomalous fetus can be made in most instances. Fetal death in utero may be established by roentgen rays, although the findings may not become apparent until several days after the death of the fetus. Placentography has been used successfully in some clinics, and the diagnosis of abdominal pregnancy can be facilitated by the use of roentgen rays. The roentgenologist and obstetrician must work as a team if the best results are to be obtained with roentgen examination in the care of the maternity patient and her child.

Corticotropin in Treatment of Nontropical Sprue.—The diagnosis of idiopathic steatorrhea in the patient described was supported by the presence of diarrhea, steatorrhea, a flat oral glucose tolerance test curve, megaloblastic anemia, and free hydrochloric acid in the gastric juice. The patient had previously responded to treatment with crude liver extract, folic acid, and vitamin B_{12}, but the cessation of therapy was followed by a relapse. At the time of writing the patient has been in clinical and hematological remission for more than 15 months following treatment with corticotropin. The corticotropin was given by intravenous infusion for 54 days. For the first 18 days of treatment he received 13.5 units of corticotropin daily. The dosage was then reduced to 10 units daily for 6 days, after which it was reduced to 5 units daily for 30 days. Adequate adrenal response to treatment was proved by the fall in fasting eosinophil counts. Throughout the period of treatment the patient was maintained on a high calorie, low salt diet with supplemental potassium. The response of this patient to corticotropin supports previous observations that adrenal steroids alter the course of idiopathic steatorrhea.

The more pronounced and prolonged effect of therapy in this case, as compared to those previously reported, may be in part due to more vigorous adrenal stimulation. Although observations published to date indicate that endogenous or exogenous adrenal steroids can alter the pathological physiology of idiopathic steatorrhea, the nature of this alteration and the manner in which it takes place is unknown. It is pointed out that adrenal insufficiency and steatorrhea may have the following disturbances in common: asthenia, hyperpigmentation, hypotension, steatorrhea, and an abnormal blood sugar response to ingested glucose. Recent studies fail to support the possibility that a causal relationship exists between adrenal insufficiency and sprue. It is assumed that the response to corticotropin in this patient was due to improved intestinal absorption of various nutrients including hematopoietic factors.

Sympathectomy in Treatment of Frostbite.—A unilateral ganglionectomy was performed in 28 men and 5 women between the ages of 22 and 65 who had bilaterally equal frostbite in both lower extremities. The untreated extremity served as a control for evaluation of the sympathectomy. Most of the patients sustained their injury after an alcoholic bout on a cold, wintry night. In 24 patients ganglionectomy was performed prior to the onset of gangrene, while the remaining 9 patients already had gangrene of varying extent involving their lower extremities. Sympathectomy did not prevent or limit the extent of gangrene when performed early, nor did it hasten healing once gangrene was established. Seven patients of the 33 had 10 subsequent admissions to the hospital for repeated frostbite, which was usually sustained in a manner similar to their initial injury. Sympathectomy did not protect the extremity against repeated cold injury. Seven patients presented themselves 3 months to 31 years after cold injury with one or more of the chronic sequelae such as paresthesias and pain, trophic ulcers, and coldness and numbness of feet. It is in the treatment of these late sequelae of frostbite that sympathectomy has its greatest application. In all patients the feet became subjectively and objectively warmer following ganglionectomy, the skin temperatures increasing 2 to 4 degrees Fahrenheit by actual measurement and oscillometric readings by up to 40%. Paresthesias and pain were relieved. Ulcers disappeared, circulation improved, and symptoms subsided. As proof of the efficacy of the procedure, results were so impressive that sympathectomy was proceeded with in the control extremity in five patients, with similar spectacular results.

The Hypothalamus and Hydrochloric Acid Secretion.—Experiments were made on monkeys to study alterations in gastric hydrochloric acid secretion induced by stimulation of the hypothalamus. The animals were anesthetized with cyclopropane and concentric bipolar electrodes were placed in the anterior or posterior hypothalamus after small burrholes were made in the cranium. Condenser discharge stimuli of 2 v. were delivered at a frequency of five per second for 30 seconds. Gastric samples were obtained through a Levin tube before stimulation and at half hour intervals for five hours thereafter, and their hydrogen ion concentrations were determined with a glass electrode pH meter. Animals had been fasted for 24 hours and the stomach emptied as completely as possible before stimulation. The anterior or posterior hypothalamus was stimulated in intact animals, 48 hours after bilateral vagotomy, 48 hours after bilateral adrenalectomy, 48 hours after bilateral adrenalectomy and vagotomy, and 48 hours after spinal cord section. In a second series of experiments, the gastric hydrochloric acid response to subcutaneous insulin and corticotropin (ACTH) was measured in intact animals 48 hours after bilateral vagotomy, and 48 hours after bilateral adrenalectomy. Results of the stimulation experiments revealed that the hypothalamus increases the secretion of gastric hydrochloric acid by two distinct and separate routes. The first originates in the anterior hypothalamus, is conducted through the vagus nerve, and is blocked only by vagotomy. The peak of its response is prompt. The second, with a later peak response, arises in the posterior hypothalamus, is conducted humorally through the pituitary-adrenal system, and is blocked only by adrenalectomy. The increase in gastric hydrochloric acid induced by administration of insulin, exhibits features of the responses to both anterior and posterior hypothalamic stimulation. It would appear, therefore, that insulin excites hydrochloric acid secretion through both channels. The administration of corticotropin to animals not operated on produced an increase in gastric acid secretion that was very similar to that resulting from posterior hypothalamic stimulation. Vagotomy had no effect on this response, while adrenalectomy abolished it completely. These data on the monkey may be expected to approximate more closely those concerning human physiological processes than others previously reported in carnivores. The authors' observations support those described in the cat and dog, and hence strengthen extrapolations of these experimental findings in man.

*Pleurodynia Outbreak in North Texas. J. A. Risser.—p. 374.

Pleurodynia Outbreak in North Texas.—Risser first recognized pleurodynia in Fannin County of northeast Texas in August, 1951, when a 35-year-old druggist telephoned at 4 a. m. saying that he could not breathe and that he was having a heart attack. Examination revealed a zone of pain with numbness along the right costal margin. Fluoroscopy showed an elevated and splinted diaphragm with no pneumothorax. The heart and pleurae were normal. Intramuscular injection of meperidine (Demerol) gave considerable relief. Another paroxysm of pain along the left costal margin was again accompanied by respiratory distress. A son, aged 3, and a daughter, aged 5, had experienced mild febrile illness with paroxysmal respiratory distress only a few days before. Looking back over records of patients seen in July, Risser found several faulty impressions: herpes zoster without eruption, coronary occlusion without electrocardiographic signs, gallbladder disease without jaundice or stones, and duodenal ulcer without roentgen ray confirmation. In a number of other patients who complained that "it hurts to breathe," he had arrived at no diagnosis, but by Aug. 7, a number of patients with this complaint were observed daily and other local physicians had dealt with similar cases. With the aid of the state health department and of a team of the National Institute of Health, studies were made on specimens of feces, blood, and throat washings. The viruses isolated from the initial group of cases, were Coxsackie B, type 3. Since this agent was isolated from the stools of 16 of 17 selected uncomplicated cases of pleurodynia in which there was evidence of antibody response, it is thought that the Coxsackie B, type 3 virus was the cause of this outbreak. The last classical cases of pleurodynia were seen in October. Counting the misdiagnosed cases of July in addition to those properly called pleurodynia, the author personally examined and prescribed for 128 cases of clinical pleurodynia. The author stresses the extreme contagiousness, pointing out that most laboratory workers who handle the virus succumb to pleurodynia. He also mentions that at the conference on poliomyelitis held in Denmark it was suggested that immunity to "devil's grip" (pleurodynia) viruses might protect against poliomyelitis.

Adolescent Kyphosis.—In the course of the examination of 1,000 young men at a recruit-training center, Dameron and Gulledge found 83 with a significant dorsal kyphosis which could not be corrected by active or passive attempt. These men were then studied more closely with a complete history, physical examination, and lateral roentgenograms of the thoracic and lumbar vertebras. Roentgenographic criteria for a diagnosis of adolescent kyphosis were: (1) anterior wedging of two or more thoracic vertebrae, (2) increased anteroposterior diameter of the affected vertebrae, and (3) irregularity of the adjacent vertebral surfaces. Twenty-two of the 83 patients did not have vertebral changes sufficient to justify the diagnosis of adolescent kyphosis, and so there remained 61 among 1,000 healthy young men who had the deformity. Adolescent kyphosis has been discussed also under such terms as Scheuermann's disease, juvenile dorsal kyphosis, and vertebral epiphysitis. Reports suggest that it occurs chiefly in males (70 to 90%). The general health of the patient is usually good and the musculature shows normal development. There may be pain in the area of the kyphosis for a few weeks early in the course of the disease. The deformity, noticed by relatives or friends, is the most frequent complaint. The sixth through the 10th thoracic vertebrae are involved most frequently. The treatment generally recommended is support of the spine by casts, braces, or bed rest to prevent accentuation of the kyphos. Results have been inconclusive. No treatment is indicated after vertebral growth has stopped.

Duodenal Diverticula.—Horsley and Vlasis review observations on 43 patients with duodenal diverticula seen at a Richmond, Va., hospital during the past 10 years. More of the diverticula occurred on the concave side of the descending duodenum, and the majority of these were false. The incidence of diverticula occurring in each portion of the duodenum in these 43 patients was as follows: in the ascending portion, 12; in the descending portion, 20; in the transverse portion, 3; in the terminal portion, 1; between the ascending and descending portions, 3; between the descending and transverse portions, 1; and between the transverse and terminal portions, 3. There were approximately as many men as women. Five of the 12 patients in whom the duodenal diverticulum was the only lesion were treated by surgical excision and improved subsequently. The remaining patients were treated medically, since the severity of their symptoms did not warrant surgical interventions or they were not suitable candidates for surgery. The remaining 31 had an associated duodenal ulcer, cholecystitis, cholelithiasis, diverticula of the colon, and/or other gastrointestinal disorders. In one case of duodenal diverticula and duodenal ulcer, the diverticula were felt to be the major lesion, and the patient was treated by excision of the diverticula and vagotomy, with relief of symptoms. Once the diagnosis has been established by roentgenologic examination, the question arises whether medical or surgical treatment is required. The symptoms observed oftenest are those either referable to the biliary tract or suggestive of duodenal ulcer. The predominant symptom is pain above and to the right of the umbilicus. The patient may also have headache, nausea, distention, water brash, vomiting, and other symptoms suggestive of biliary dyskinesia. This pattern of symptoms referable to the biliary tract probably results from the fact that usually the diverticulum is in the same segment as the biliary tract. Pressure over the diverticulum may cause radiation of pain posteriorly to the back and/or below the costovertebral angle. The authors feel that surgical treatment is indicated under the following conditions: when the symptoms persist despite conservative therapy; when barium is retained in the diverticulum for four hours or longer; when the diameter is more than 3 cm.; and when the diverticulum contains bezoars. After briefly commenting on the surgical approach, the authors describe two cases in which surgical excision of the diverticulum was followed by improvement.

Coxsackie Viruses in Poliomyelitis.—It was demonstrated that Coxsackie viruses were widespread in Sydney during the summer of 1950-1951, when poliomyelitis occurred in epidemic proportions. This paper reports observations on three patients, two paralytic and one nonparalytic, from whom poliomyelitis viruses could not be isolated by monkey inoculation. Coxsackie viruses were isolated from the feces of these three patients. Antibodies to the homologous virus developed in these patients to high titers. One strain of the Coxsackie viruses is related to Dalldorf group A type 4, one to a previously described Australian type (W32) and the third represented a new serological type. It is of interest to determine whether the Coxsackie viruses, isolated from the feces and also responsible for the antibody response, bear any relationship to the disease process or the symptoms (especially paralysis) observed at the time of virus isolation. No attempt has been made to isolate either Coxsackie or poliomyelitis viruses from skeletal muscle of patients, and a Coxsackie virus has not been isolated from human brain or cord post mortem.

Coxsackie Viruses Associated with an Outbreak of Encephalitis.—In the course of epidemiological studies with poliomyelitis and Coxsackie viruses in Australia it became evident that in January, 1952 (midsummer), a dramatic increase had occurred in the number of cases of encephalitis. This communication describes the isolation and properties of a hitherto undescribed infective agent believed to be closely associated with the outbreak. The laboratory examinations of the outbreak were carried out many weeks after its decline. It has not been proved that the Coxsackie viruses isolated were responsible for the outbreak as none was isolated from central nervous system material. The circumstantial evidence (the isolation of one antigenic type of virus from the feces in a large number of cases and the demonstration of antibodies to the virus in the patient's serum in all cases) is such as to indicate a very close relationship. It is realized, however, that the technique of monkey inoculation for the recovery of poliomyelitis viruses is by no means perfect. As this report includes (with the exception of contacts) only hospitalized patients, an incomplete picture of the outbreak is presented. The outbreak seemed widespread in the Sydney metropolitan area, sufficiently so as to cause comments in the lay press, and a sudden rise in antibody in pooled human serum to the virus thought to be responsible for the outbreak. The demonstration of antibodies to the etiological agent in pooled human serum immediately prior to the time when the disease first became clinically apparent may be explained by the assumption that there was an increase in the number of carriers of the infective agent at this time. The infective agent was shown to be present only in the feces. It was filtrable and had some of the properties of the Coxsackie group of viruses. Because all strains tested produced infection only in suckling mice with resulting lesions in the central nervous system, it was assumed that the agent was a Coxsackie virus. All strains isolated differed slightly from the group B Coxsackie viruses and differed markedly from the group A Coxsackie viruses so far isolated. The differences were sufficient to warrant a temporary designation of Coxsackie group C.

Streptomycin Resistance in Tuberculosis Patients Treated with *p*-Aminosalicylic Acid.—In the treatment of pulmonary tuberculosis with streptomycin alone the emergence of strains of tubercle bacilli resistant to the drug is well known. That the same thing happens when isoniazid is used alone is now established, but the possibility of resistant strains emerging when pulmonary tuberculosis is treated with sodium or calcium *p*-aminosalicylate alone has received much less attention. This paper revealed that tubercle bacilli from eight of nine patients who had previously received the sodium salt of *p*-aminosalicylic acid alone for pulmonary tuberculosis were found to be resistant to the drug. The original course of treatment lasted from 6 weeks to 16 months, and the interval between the finish of the course and the resistance tests varied from a few days to 39 months. When treated daily with streptomycin and the sodium salt of *p*-aminosalicylic acid, streptomycin-resistant tubercle bacilli emerged in all the eight patients whose bacilli were resistant to the sodium *p*-aminosalicylate before the start of the combined treatment. The streptomycin-resistant bacilli were obtained in six out of the eight cases within three months on combined treatment, in the seventh after four months, and in the eighth after five months. By contrast a slightly streptomycin-resistant organism was isolated after five months' treatment from only one out of six similar cases whose organisms were sensitive to the sodium salt of *p*-aminosalicylic acid at the start of the combined course. Five of the cases had had no previous treatment with the sodium salt of *p*-aminosalicylic acid alone. It is concluded that tubercle bacilli that are resistant to the sodium salt of *p*-aminosalicylic acid are likely to develop if patients with pulmonary tuberculosis are treated with this drug alone; that the resistant organisms may persist for long periods; and that, if the patients are later treated with the sodium salt of *p*-aminosalicylic acid and streptomycin, the sodium salt of *p*-aminosalicylic acid will then no longer prevent or diminish the emergence of streptomycin-resistant bacilli.

Peptic Ulcer in Women.—Many observers assert that symptoms of peptic ulcer and presumably its activity are influenced by menstruation and pregnancy. The evidence presented here was obtained by interviewing 400 women in whom peptic ulcer had been demonstrated. The ulcer was duodenal in 330 cases and gastric in 70. The patients' ages ranged from 21 to 74 years. The symptoms in most cases were of more than five years duration. Often the patient volunteered some information. If not, the standard questions were asked, "Have you noticed any relationship between your ulcer and menstrual period/pregnancy/menopause? Was your ulcer made better or worse, or did it remain the same?" Apart from paraphrasing these questions according to the patient's understanding of them, no further attempt was made to elaborate a correlation. Of the 400 patients, 291 had had ulcer symptoms before the menopause. In this group 81 noted some relationship between menstruation and ulcer symptoms. In all the symptoms were worse for a few days or a week before the onset of menstruation. In eight the ill-effect persisted during the menstrual period, but none reported increase of ulcer symptoms during the postmenstrual phase. Relief of symptoms occurred in nearly 90% of pregnancies. In most of them the remission occurred early in pregnancy and persisted until term. Those patients who gained no relief had a higher proportion of abnormalities such as albuminuria and hyperemesis. Recurrence of ulcer symptoms was common after parturition especially during the first six months. An unduly large proportion of ulcers start, flare up, or undergo complications at or about the time of the menopause.

Cerebral Hemispherectomy in Cerebral Palsy.—Hemispherectomy was performed in a 17-year-old girl, who had congenital hemiplegia, frequent epileptic seizures, mental retardation, and aggressive behavior. The girl had been under observation since 1944. She was born after a difficult labor and had generalized convulsive seizures shortly after birth. From the age of 2 years she had had frequent Jacksonian attacks, involving the right half of the body. Anticonvulsive drugs had little effect. Gradually a right spastic hemiplegia developed. In 1945, the left occipital lobe, which harbored a large porencephalic cyst, was excised, but this intervention did not change her seizures, and the left-sided spastic hemiparesis, mental retardation, and aggressive behavior had become severer. Surgical ablation of the left hemisphere was performed in January, 1952, and resulted in complete cessation of the epileptic seizures, alleviation of spasticity in the paretic right extremities, and marked mental improvement. The electroencephalographic records prior to operation showed an area of depressed electrical activity in the left occipital region. There was a zone of impaired electrical activity, displaying irritative features in the left posterior parietal and posterior inferior temporal regions. Hemispherectomy brought about normalization of the electrical activity of the remaining right hemisphere. A short time later, electrical brain rhythms could also be recorded from the left half of the skull. This activity, of low amplitude at the beginning, increased gradually, finally approaching the voltage of activity of the right hemisphere. It is suggested that the sources of this activity are the remaining basal ganglions, particularly the optic thalamus of the extirpated left hemisphere.

Hypoalbuminemia in Complications Resulting from Mercurial Diuretics.—This paper discusses various complications that may result from the use of mercurial diuretics such as loss of minerals, chlorides and water, attacks of gout, renal complications, thromboses, agranulocytosis, and avitaminosis. Reported cases of death after intravenous use of mercurial diuretics are reviewed. Summary of clinical and experimental evidence suggests direct toxic action of the mercury on the myocardium. Four additional cases (two of them fatal) of toxicity due to mercurial diuretics are presented. In these cases toxic manifestations followed immediately after intravenous injection and were apparently caused by direct action on the myocardium. A common factor in all four cases was hypoalbuminemia. Since hypoalbuminemia is noted, or can be inferred, in a large proportion of cases of sudden death after intravenous use of mercurial diuretics, it is suggested that hypoalbuminemia may predispose to such accidents.

Blood Picture After Operation for Portal Hypertension.—This report is concerned with hematological problems of the syndrome of portal hypertension. Observations in 46 cases of portal hypertension treated either by splenectomy alone or by splenectomy and splenorenal anastomosis indicate that the persistent leukopenia and thrombocytopenia found in this syndrome are rapidly relieved by splenectomy. These findings suggest a relationship between the levels of the leukocytes and platelets in the peripheral blood and enlargement of functional overactivity of the spleen, and is, in accordance with the hematological concept of "hypersplenism." Portacaval anastomosis without splenectomy was done in seven cases of portal hypertension. In three of these, the spleen became smaller from relief of venous congestion, but the pulp hyperplasia persisted, and in no case was the blood picture improved. The effects of ligation of the splenic arterial supply by various operations were observed in five cases. The spleen did not decrease in size after any of these operations. Histological examination of the spleens of three patients in whom the splenic artery had been ligated and divided 15, 18, and 28 months previously, showed either the typical changes of portal hypertension or complete localized infarction. The generalized atrophy of splenic tissue described by other workers was not observed. After splenic arterial ligation no improvement was noted in the blood picture except in one case in which there was extensive infarction of the spleen. Neither relief of portal venous congestion by a portal-systemic venous anastomosis nor reduction in the blood supply to the spleen by arterial ligation improves the leukopenia or thrombocytopenia characteristic of portal hypertension. In contrast the changes can be regularly relieved by splenectomy. Hence it may be inferred that the reduction in the leukocytes and platelets is directly related to some influence derived from the cellular components of the enlarged spleen. In no case was there any evidence that any of the operations benefited the red blood cell and hemoglobin levels other than by control and prevention of esophageal bleeding.

*Role of Nervous Factors in Causation of Peptic Ulceration. B. Robinson. —p. 624.

Causation of Peptic Ulceration.—Robinson traces pathways from various parts of the cortex to the gastric mucosa, suggests mechanisms through which they may affect it, and considers changes that may set these mechanisms into pathological action. Many peptic ulcer patients are outwardly aggressive, ambitious and independent, refusing help and burdening themselves with all kinds of responsibilities. The more they strive for independence and responsibility, the stronger is the unconscious desire to be cared for and to return to the oral stage. Food is then wanted not to satisfy hunger but as a symbol for love and help. This explains also the relief derived from treatment in hospital, as there the patient is able to shed his responsibilities and acquire by way of a seemingly legitimate, socially acceptable compromise, the care, help, attention and security he craves. There seems no doubt that the accepted methods of treatment with rest, sedation, antacids, atropine and diet must be followed during active phases. However, this alone is inadequate. The symptoms must be considered only as indicators of the underlying personality disturbance and continued attention to them will only fix them and contribute to their perpetuation. Time must be spent in the elaboration of the social history and in discovering the patient's attitude towards his environment. Organic nervous lesions are rare in peptic ulceration, but psychological deviations are common and are related, in part at least, to the importance of the alimentary system to the emotional life of the individual. Psychotherapy is a most useful preventive measure during the period of functional symptoms preceding the development of the ulcer and is an essential component of treatment when it is established.

*Pathology and Treatment of Simple, Acute, and Chronic Pneumothorax. L. Biancalana and A. E. Paletto.—p. 209.

Pathology and Treatment of Various Forms of Spontaneous Pneumothorax.—Simple spontaneous pneumothorax appears suddenly in apparently healthy persons, the lesions responsible for it being generally asymptomatic at the time of the onset. This type of pneumothorax has a benign and afebrile course without formation of exudate and usually heals spontaneously. The causative factors of the attack are in most cases ruptured subpleural cysts and localized blebs and bullae. Often the lung expands again; when it does not the condition becomes chronic. The factors which account for the failure of the lung to reexpand are persistence of a bronchial fistula because of a ruptured congenital cyst, intrapleural adhesions, pulmonary and bronchial scar tissue, and often empyema and hemothorax. The acute form of spontaneous pneumothorax is characterized by pain in the chest and a severe dyspnea, making a correct diagnosis easy. The exact cause of spontaneous pneumothorax is best established by thoracoscopy, intrapleural pressure measurements, and bronchography. Bronchoscopy is usually of no diagnostic help. Since cysts and blebs may represent the preparatory phase of a simple spontaneous pneumothorax, their early diagnosis and treatment may prevent the onset of the pneumothorax. Bed rest is the best treatment for simple and acute pneumothorax, but it is ineffectual in chronic cases. The two main types of treatment for chronic pneumothorax are artificial pleurisy produced by irritants introduced into the pleural cavity and surgical procedures. Various types of irritants (including guaiacol, iodoform, iodized oil, dextrose solutions, and silver nitrate) have been placed into the pleural cavity to produce a violent pleurisy accompanied by pleural effusion and fibrin deposition. These close the aperture in the parenchyma, which then expands again. This conservative method is painful and has a severe effect on the patient's general condition, since it causes fever and greatly impairs his respiratory function because of the ensuing fibrothorax. For this reason surgical treatment is preferred. Phrenic paralysis was introduced by Weiss to relax the diaphragm and decrease the tension of the lung and thus permit the pulmonary aperture to heal. The results were not successful. Today chronic pneumothorax is treated either by thoracoscopy or thoracotomy. The latter is the treatment of choice. It is contraindicated only in the presence of bilateral bullae, and in this case induction of pleurisy is the best treatment.

Physiological Correction of Asthmatic Terrain.—Patients with asthma have certain functional disturbances predisposing them to acute attacks. These disturbances include an almost constant reduction in the biochemical excitability of the respiratory centers, the very frequent existence of reflex hyperexcitability of the sympathetic centers, especially the vasopulmonary sympathetic centers, and in some cases a reduction in the respiratory capacity of the blood. Excellent therapeutic results have followed the physiological correction of these disturbances with centropneine, a hormone recently isolated from the pancreas. Careful study of 200 patients with asthma treated by this method showed substantial improvement in 161; attacks were either suppressed or reduced in intensity or frequency. The product used in treating these patients, however, was not entirely free from vagotonin, and it was noted that the greater the amount of vagotonin present, the less satisfactory were the results. Further work culminated in the production of a vagotonin-free preparation of centropneine. The effect of this refined preparation was studied in a series of 142 men, women, and children with varying types of asthma. Adults were given from 10 to 30 respiratory units of centropneine before each of three meals; for children, the dose was reduced to from 5 to 10 units. Significant improvement was observed in 125 patients treated for periods of from two weeks to six months; asthmatic attacks, latent oppression, dyspnea on effort, and cough disappeared completely in 40. Several weeks and sometimes months of regular and continuous treatment are usually needed for modification of the asthmatic predisposition. Prolonged treatment presented no difficulty because centropneine, when free from vagotonin, is well tolerated. Treatment was unsuccessful in 17 patients, 7 of whom had severe, inadequately treated respiratory infections. Immoderate use of sympathicomimetic drugs and those depressing the respiratory centers was apparently responsible for failure in eight cases; in two others, predominance of an allergic factor led to partial failure. Supplementary treatment with antibiotics or vaccines and, especially, mineral waters rich in sulphur, may prove highly advantageous.

Combined Antibacterial Medication in Pulmonary Tuberculosis.—The effectiveness of the combined treatment of pulmonary tuberculosis depends primarily on the efficacy of the most active drug in the combination. The belief that the efficacy of one drug is increased by the presence of another is not borne out by either laboratory or clinical tests; the synergistic effect obtained is due to the fact that the supplementary drug affects bacteria that would otherwise be left untouched. The use of drugs in combination is chiefly beneficial because it delays or prevents the development of drug-resistant strains of bacilli, thus making prolonged treatment possible and increasing the chances of cure. These results can only be obtained when the drugs to which the bacilli are sensitive are given together from the beginning of the treatment and *in doses that would be effective for each alone;* dosage should never be reduced because the drugs are combined. The advantages of the combined treatment are particularly apparent in the highly bacilliferous forms of tuberculosis in which resistance to a single drug develops rapidly.

Transmission of Hepatitis by Blood and Plasma Transfusions.—Of 189 patients who were given transfusions of whole blood in 1950 and 1951, only 1 had icterus within six months after the transfusion. The risk of hepatitis following infusion of whole blood is small and is probably far below 1%. The blood of seven donors who had jaundice one to five years before was tranfused to eight recipients. The blood of additional 77 donors who had had jaundice five or more years before they donated blood was transfused to 92 recipients. None of these 100 recipients had hepatitis within six months after the transfusion. Although the number is too small for definite conclusions, these figures suggest that convalescent carriers are of little importance in transmission of hepatitis. The management of the blood donor service of the Swiss Red Cross decreed in 1952 that any person who had once had jaundice should be excluded from its donor service. Although this resolution means an average 8% loss of blood donors, the authors agree with it because it is well established that some persons are carriers of hepatitis virus for several years and the question of the average duration of carrying convalescent virus has not been answered. If for some reason it should not be possible to exclude donors who once had had jaundice, their blood should be used only for single transfusions but not for the production of a pooled plasma. Of 189 patients admitted to the City Hospital of Basel who had been given 362 transfusions of dried plasma and 516 transfusions of whole blood, 8 had inoculation hepatitis for which the dried plasma was held responsible. The incidence of hepatitis with respect to the number of recipients was 4.2%, and with respect to the number of administered dried plasma units 2.2%. Of 90 recipients of 135 dried plasma units who did not receive whole blood, 4 had epidemiologically established inoculation hepatitis caused by dried plasma. The incidence of hepatitis with respect to the number of recipients, was 4.4% and with respect to the number of administered dried plasma units 2.9%. Of 126 plasma pools, 4 were definitely icterogenic and 2 others possibly were. Since none of the donors who had contributed to the plasma pools had had icterus, it may be assumed that healthy carriers rather than incubation virus carriers played the most important part in the contamination of the plasma pools with hepatitis virus. The conclusion for the practitioner is that pooled plasma should be employed only in cases in which because of the gravity of the patient's condition the risk of late damage caused by inoculation hepatitis appears to be insignificant as compared to the expected therapeutic usefulness of the pooled plasma.

*Clinical and Physiopathological Considerations in Treatment of Angina Pectoris with Heparin. E. Donzelot, H. Kaufmann and J. M. le Bozec. —p. 1549.

Electrocardiography in Subacute Infectious Endocarditis.—Electrocardiograms made routinely before, during, and after treatment in a series of 200 patients with subacute infectious endocarditis were studied to determine their diagnostic and prognostic value. A diagnosis of subacute infectious endocarditis was rarely established when auricular fibrillation or acquired valvular heart disease affecting the right side of the heart was reflected in the electrocardiograms; acquired heart disease affecting the left side of the heart, on the other hand, was frequently complicated by subacute infectious endocarditis. Signs of acute cor pulmonale and myocardial impairment appearing in electrocardiograms made during treatment often presaged irreversible heart failure. Electrocardiographic changes are most pronounced in resistant cases and those in which treatment is late. The abacterial forms of the disease show a preponderance of changes; in electrocardiograms made before treatment was started, cardiac insufficiency was found in 15% of the patients with negative blood cultures as compared with 4.5% of those with positive blood cultures, while during treatment heart failure occurred in 22% of the patients with negative cultures and in only 11% of the others. Bundle-branch block and coronary impairment predominate in patients with aortic involvement, possibly because the severe, primary forms of subacute infectious endocarditis are almost always localized in the aortic valves. The principal changes in patients with mitral involvement are those indicative of acute cor pulmonale and, later, auricular fibrillation. Fear of possible complications must not be allowed to interfere with the use of penicillin, which offers the only hope of cure.

Treatment of Angina with Heparin.—Study of 53 patients, most of whom have been followed for a year, shows that attacks of pain can be suppressed by the intravenous injection of a very small dose of heparin (e. g., 25 mg.) in about 70% of patients with angina pectoris. Improvement was secured in nearly 100% of those with typical angina occurring on effort and relieved within about 5 minutes by glyceryl trinitrate; the results in patients with bundle-branch block or a sequela to myocardial infarction whose chest pain was not clearly connected with effort or clearly relieved by glyceryl trinitrate were less satisfactory. Patients who respond promptly to glyceryl trinitrate are almost always benefited by heparin; when glyceryl trinitrate is ineffective, heparin treatment is not likely to be successful. The same patients benefit by both remedies, but glyceryl trinitrate is an emergency treatment to be used during an anginal attack, while heparin is a basic treatment applicable to the anginal state. The efficacy of heparin is greatest when the anginal attacks are clearly due to effort; patients in whom they are related to emotion also prove responsive to its action. Atypical pain accompanied by vasomotor phenomena of the kind found mostly in hypertensive patients is not affected by either heparin or glyceryl trinitrate. Three patients with calcified aortic stenosis who had for a long time had frequent attacks and who required several glyceryl trinitrate tablets daily were benefited by heparin to such an extent that within the first days of treatment glyceryl trinitrate became unnecessary. The effectiveness of heparin treatment does not seem to be dependent on the blood picture; excellent results were obtained in a patient in whom hypocoagulability was pronounced, and sustained relief of anginal attacks were secured in another patient with persistent hypercoagulability. Patients receiving heparin must follow the usual tranquil regimen, even in the absence of attacks; although their tolerance for exertion is increased, a severe attack may be produced by any unusual effort. Improvement is usually constant as long as the injections are continued, but anginal attacks recur when treatment is suspended even after a period of several months. Failure of heparin to produce good results within three weeks indicates that the dose should be changed; addition of another drug, such as ethyl biscoumacetate (Tromexan ethyl acetate), may also prove advantageous. Laboratory studies showing that the effects of heparin injection are antagonistic to those of sympathetic excitation suggest that the action of heparin, though exerted at a different level, is similar to that of the sympathicolytics. Heparin apparently influences the humoral effects of nervous excitation, while the sympathicolytics tend to suppress the excitation itself.

Tumors of Small Intestine.—Faber and his associates described 45 cases of tumor of the small intestine in patients aged between 40 and 70. Fifteen tumors were benign, 10 were sarcomas, 9 of which were apparently primary in the small intestine and one presumably metastatic, and 20 were carcinomas. While the benign tumors and sarcomas were usually distributed throughout the small intestine, the carcinomas showed a marked tendency to occur at the ends of the intestine. In 12 cases there were no symptoms until an acute abdominal catastrophe occurred, in 11 an acute abdominal crisis occurred after symptoms of some duration, in 12 the symptoms were those generally seen in tumors elsewhere in the gastrointestinal tract, and in 9 cases the only sign was bleeding, either typical melena or occult with anemia. The prognosis for tumors of the small intestine has greatly improved in recent years. Careful examination including vaginal exploration and roentgen examination of the small intestine as a rule gives the diagnosis. If the results were negative and particularly if occult bleeding continues, exploratory laparotomy is necessary.

*Irradiation Therapy of Carcinoma of Uterine Cervix. E. Maier.—p. 412.

Irradiation Therapy of Carcinoma of the Breast.—Between 1937 and 1947, 580 women and 2 men with carcinoma of the breast were given irradiation treatment at the central roentgen institute of the Vienna-Lainz Hospital. Of these, 234 with stage 1 to 3 carcinoma, according to Steinthal's classification, were given intensive local irradiation between 1937 and 1945 (first period of treatment), 273 with stage 4 carcinoma (generalized carcinosis) were given small dose-irradiation treatment of the entire body between 1938 and 1947 (second period of treatment), and 75 patients with stage 1 to 3 carcinoma received combined intensive local irradiation and prophylactic irradiation of the entire body between 1945 and 1947 (third period of treatment). In patients with carcinoma of stage 1 to 3 treated during the first period, the technique of fractionated local irradiation consisted of the usual three field-irradiation with 175 kv., 6 ma., 0.5 mm. Cu plus 1 mm. aluminum filter at a distance of 40 cm., a field dose of 240 r, each field repeated seven times, one field daily, with a total serial dose of 5040 r surface. Irradiation treatment was instituted on the third postoperative day. The local series were not repeated. Of the 234 patients of the first irradiation period 117 (50%) obtained a five year cure. In the 273 patients with stage 4 carcinoma treated during the second period, a permanent cure could not be expected as a result of the irradiation therapy; despite that, an average survival time up to two years with working capacity maintained in the complete or nearly complete absence of pain, was obtained by entire body-irradiation with alternating posterior and anterior entire body-fields, 175 kv. at the tube, 4 ma., 0.5 mm. Cu plus 1 mm. aluminum filter, at a distance of 150 cm., with a dose of 24 r per single session. A series consisted of 10 single sessions. The interval between two series varied from three months to four weeks according to tolerance. Of the 75 patients treated during the third treatment period, 39 (52%) obtained a five year cure. This increased ratio of five year recoveries was obtained by the combined treatment with local irradiation (seven times 240 r) and an entire body-irradiation series of 10 times 24 r with alternating anterior and posterior fields two months after the last local irradiation and repeated twice at six week intervals.

Irradiation Treatment of Cancer of Uterine Cervix.—Between 1937 and 1946, 1,410 women with carcinoma of the uterine cervix were examined at the irradiation department of the Vienna-Lainz hospital. Only 1,048 received complete irradiation treatment, while the large number of 362 patients did not, because of the political events and the war occurring during the reported period. Of the 1,410 patients, 56 had stage 1 carcinoma of the cervix uteri according to the classification of the 1937 committee of the League of Nations, 139 stage 2, 875 stage 3, and 340 stage 4. Treatment consisted of near-radium irradiation and radium irradiation at a distance of 6 or 10 cm., depending on the location of the tumor. The near-radium irradiation was carried out according to Forssell's principle, with capsule-shaped vaginal applicators equipped with 80 mg. radium element and with an intrauterine probe equipped with 40 mg. radium element. This treatment was practiced in three stages, i. e., vaginal application for 30 hours, repeated for 24 hours after an interval of 14 days, and followed by treatment with the intrauterine probe for 72 hours after a second interval of 14 days. Radium treatment at a distance of 6 cm. was given with 6.93 r per minute at the skin surface and at a distance of 10 cm. with 3.4 r per minute. Four field-irradiation was used; one field received on the average at the distance of 6 cm. a total dose of 12,500 r in 30 hours. Half of the surface dose was obtained with the 6 cm. distance and a 3 cm. depth or with a distance of 10 cm. and a 4 cm. depth. One field was irradiated daily for two hours, so that the total duration of treatment varied from six to eight weeks, and the lateral parametriums received a total dose of approximately 2,000 r. Of the 1,048 patients who have completed their treatment, 276 were symptom-free for five or more years, i. e., a relative average recovery rate of 39.2% in the four stages of the disease. This recovery rate was somewhat smaller than that of 41.7% obtained during the period of 1935 to 1938; the less favorable results were due to the war and undernourishment. The results obtained with irradiation therapy for carcinoma of uterine cervix at the Vienna-Lainz hospital correspond with those obtained at other large irradiation institutes according to Heymann's annual report of 1951. Satisfactory results did not depend only on treatment but also on the periodic control of the patients once treated and on the general care they had received. The combination of all favorable factors promise a successful campaign against carcinoma of the uterine cervix.

pressing the respiratory centers was apparently responsible for failure in eight cases; in two others, predominance of an allergic factor led to partial failure. Supplementary treatment with antibiotics or vaccines and, especially, mineral waters rich in sulphur, may prove highly advantageous.

Combined Antibacterial Medication in Pulmonary Tuberculosis.—*The* effectiveness of the combined treatment of pulmonary tuberculosis depends primarily on the efficacy of the most active drug in the combination. The belief that the efficacy of one drug is increased by the presence of another is not borne out by either laboratory or clinical tests; the synergistic effect obtained is due to the fact that the supplementary drug affects bacteria that would otherwise be left untouched. Tumors of Small Intestine.—Faber and his associates described 45 cases of tumor of the small intestine in patients aged between 40 and 70. Fifteen tumors were benign, 10 were sarcomas, 9 of which were apparently primary in the small intestine and one presumably metastatic, and 20 were carcinomas. While the benign tumors and sarcomas were usually distributed throughout the small intestine, the carcinomas showed a marked tendency to occur at the ends of the intestine. In 12 cases there were no symptoms until an acute abdominal catastrophe occurred, in 11 an acute abdominal crisis occurred after symptoms of some duration, in 12 the symptoms were those generally seen in tumors elsewhere in the gastrointestinal tract, and in 9 cases the only sign was bleeding, either typical melena or occult with anemia. The prognosis for tumors of the small intestine has greatly improved in recent years. Careful examination including vaginal exploration and roentgen examination of the small intestine as a rule gives the diagnosis. If the results were negative and particularly if occult bleeding continues, exploratory laparotomy is necessary.

*Irradiation Therapy of Carcinoma of Uterine Cervix. E. Maier.—p. 412.

Irradiation Therapy of Carcinoma of the Breast.—Between 1937 and 1947, 580 women and 2 men with carcinoma of the breast were given irradiation treatment at the central roentgen institute of the Vienna-Lainz Hospital. Of these, 234 with stage 1 to 3 carcinoma, according to Steinthal's classification, were given intensive local irradiation between 1937 and 1945 (first period of treatment), 273 with stage 4 carcinoma (generalized carcinosis) were given small dose-irradiation treatment of the entire body between 1938 and 1947 (second period of treatment), and 75 patients with stage 1 to 3 carcinoma received combined intensive local irradiation and prophylactic irradiation of the entire body between 1945 and 1947 (third period of treatment). In patients with carcinoma of stage 1 to 3 treated during the first period, the technique of fractionated local irradiation consisted of the usual three field-irradiation with 175 kv., 6 ma., 0.5 mm. Cu plus 1 mm. aluminum filter at a distance of 40 cm., a field dose of 240 r, each field repeated seven times, one field daily, with a total serial dose of 5040 r surface. Irradiation treatment was instituted on the third postoperative day. The local series were not repeated. Of the 234 patients of the first irradiation period 117 (50%) obtained a five year cure. In the 273 patients with stage 4 carcinoma treated during the second period, a permanent cure could not be expected as a result of the irradiation therapy; despite that, an average survival time up to two years with working capacity maintained in the complete or nearly complete absence of pain, was obtained by entire body-irradiation with alternating posterior and anterior entire body-fields, 175 kv. at the tube, 4 ma., 0.5 mm. Cu plus 1 mm. aluminum filter, at a distance of 150 cm., with a dose of 24 r per single session. A series consisted of 10 single sessions. The interval between two series varied from three months to four weeks according to tolerance. Of the 75 patients treated during the third treatment period, 39 (52%) obtained a five year cure. This increased ratio of five year recoveries was obtained by the combined treatment with local irradiation (seven times 240 r) and an entire body-irradiation series of 10 times 24 r with alternating anterior and posterior fields two months after the last local irradiation and repeated twice at six week intervals.

Irradiation Treatment of Cancer of Uterine Cervix.—Between 1937 and 1946, 1,410 women with carcinoma of the uterine cervix were examined at the irradiation department of the Vienna-Lainz hospital. Only 1,048 received complete irradiation treatment, while the large number of 362 patients did not, because of the political events and the war occurring during the reported period. Of the 1,410 patients, 56 had stage 1 carcinoma of the cervix uteri according to the classification of the 1937 committee of the League of Nations, 139 stage 2, 875 stage 3, and 340 stage 4. Treatment consisted of near-radium irradiation and radium irradiation at a distance of 6 or 10 cm., depending on the location of the tumor. The near-radium irradiation was carried out according to Forssell's principle, with capsule-shaped vaginal applicators equipped with 80 mg. radium element and with an intrauterine probe equipped with 40 mg. radium element. This treatment was practiced in three stages, i. e., vaginal application for 30 hours, repeated for 24 hours after an interval of 14 days, and followed by treatment with the intrauterine probe for 72 hours after a second interval of 14 days. Radium treatment at a distance of 6 cm. was given with 6.93 r per minute at the skin surface and at a distance of 10 cm. with 3.4 r per minute. Four field-irradiation was used; one field received on the average at the distance of 6 cm. a total dose of 12,500 r in 30 hours. Half of the surface dose was obtained with the 6 cm. distance and a 3 cm. depth or with a distance of 10 cm. and a 4 cm. depth. One field was irradiated daily for two hours, so that the total duration of treatment varied from six to eight weeks, and the lateral parametriums received a total dose of approximately 2,000 r. Of the 1,048 patients who have completed their treatment, 276 were symptom-free for five or more years, i. e., a relative average recovery rate of 39.2% in the four stages of the disease. This recovery rate was somewhat smaller than that of 41.7% obtained during the period of 1935 to 1938; the less favorable results were due to the war and undernourishment. The results obtained with irradiation therapy for carcinoma of uterine cervix at the Vienna-Lainz hospital correspond with those obtained at other large irradiation institutes according to Heymann's annual report of 1951. Satisfactory results did not depend only on treatment but also on the periodic control of the patients once treated and on the general care they had received. The combination of all favorable factors promise a successful campaign against carcinoma of the uterine cervix.

BOOK REVIEWS

Atlas of Medical Mycology. By Emma Sadler Moss, B.S., B.M., M.D., Director, Department of Pathology, Charity Hospital of Louisiana at New Orleans, and Albert Louis McQuown, B.S., B.M., M.D., Pathologist, Our Lady of Lake Sanitarium, Baton Rouge, Louisiana. Cloth. $8. Pp. 245, with 248 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

This book does not constitute a major contribution to the literature of medical mycology. It does, however, constitute, particularly for the uninitiated, a useful volume, because of the number of pictures included and, in some instances, their high caliber. The text of the book appears to have been drawn from other more lengthy texts or manuals in the field and actually constitutes a synopsis. The subject is dealt with in terms of the diseases that fungi produce; consequently there is little continuity or over-all plan. A more constructive approach would have been an adequate verbal consideration of the field joined with the excellent pictures that are presented. The field is at present in need of an adequate reference of this type, but the present book does not answer this need. The subject immunology of fungi could bear much more extensive treatment, as could the basic biology of the organisms themselves. The book does seem to be adequate, although far from complete, in considering the clinical aspects of the individual diseases presented.

History of Anesthesia: With Emphasis on the Nurse Specialist. By Virginia S. Thatcher. Cloth. $5. Pp. 289, with 22 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

In this excellent reference book, the author emphasizes the position nurses have attained in the conquest of pain and presents arguments as to the philosophical, historical, anthropological, and legal basis for nurses in the field of anesthesia. Little reference is made to the history of anesthesia other than its application to nurses. Special emphasis is placed on the neglect of anesthesia as an art and science in the latter half of the 19th and early first quarter of the 20th centuries, with the duties of the anesthetist being assigned to the lowest ranking doctor. Eventually, nurses were pressed into service and handled anesthesia administration commendably because of their greater interest in the work. More attention is given to the development of the art of anesthesia than to the discovery of agents and techniques. The second half of the book deals with the story of the American Association of Nurse Anesthetists and its founders.

There has been a liberal use of footnotes and an index is appended, both of which will make this work valuable as a reference to any one interested in the role nurses have played in the history of anesthesia. The author seems most enthusiastic about her subject and has presented a convincing argument for the continued presence of nurses in the field of anesthesia administration.

Wiederherstellungschirurgie und Traumatologie. Jahrbuch [1]. Redactor: M. Lange. Editores: A. de Araujo, et al. [In German, English and French.] Cloth. 36 Swiss francs. Pp. 262, with illustrations. S. Karger, Holbeinstrasse 22, Basel, 1953.

This is an annual survey of reconstructive surgery and traumatology that records progress in the field. Each subject is discussed in German, English, and French. The various topics are presented by authorities who project their own views and personal experiences. When opinions of these surgeons differ widely a member of the editorial board has appended a critical comment. During the last 10 years surgeons in many different countries have made important contributions in reconstructive surgery of the locomotor system; many of these are included. Emphasis has been placed on the value and limits of intramedullary pinning, aseptic necrosis of the femoral head after nailing, and treatment of irreparable nerve palsy. The following discussions deserve special commendation: Intramedullary Pinning, Complication, and Technique by F. H. Vom Saal; Traitement des nécroses traumatiques de la tête du fémur by R. Merle d'Aubigné; Reconstruction Operations for Ulnar Paralysis when the Nerve is Irreparable by S. Bunnell; Die Behandlung der poliomyelitischen Lähmung des Daumens by A. Steindler; and Median and Ulnar Nerve Injuries by J. W. Littler. This international yearbook is a step in the right direction, since it presents a cooperative effort on the part of leading surgeons in different countries. The trilingual approach should make it valuable to those who are deficient in one or two of the languages included.

Your Arthritis: What You Can Do About It. By Alfred E. Phelps, M.D. Second edition. Cloth. $3. Pp. 192, with illustrations by James Macdonald. William Morrow & Company, Inc., 425 Fourth Ave., New York 16, 1953.

This small volume has been revised to include recent developments in the field of rheumatology. The book was written for the lay person with arthritis, to help him to understand better the nature of this disease and to aid him to appreciate the problems involved in his treatment. It covers briefly the historical background of arthritis, prevalence of the disease, anatomy of articular structures, treatment of various types of arthritis, and prevention of deformities. There is a discussion of corticotropin, cortisone, and hydrocortisone, and a detailed review of their discovery. The book is printed in large, clear type and has a number of anatomic illustrations. The style is easy to follow.

The author fails, however, to achieve his objective in that the illustrations and text are far too technical for the average lay person. The book is too elementary to be used by physicians or medical students and is too academic to be of any help to the arthritic patient in understanding his ailment. It is difficult to see how a person with any type of arthritis would benefit from a detailed account of the discovery of the hormonal drugs or from an involved discussion of the acid-alkali balance in the blood. The subject of rheumatology is briefly and superficially covered in this volume, but it is doubtful if the arthritic patient would learn how to live with his disease from reading it.

Textbook of Public Health (Formerly Hope and Stallybrass). By W. M. Frazer, O. B.E., M.D., Ch.B., Medical Officer of Health, City and Port of Liverpool, England. Thirteenth edition. Cloth. $8.50. Pp. 663, with illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; E. & S. Livingstone, 16 and 17 Teviot Pl., Edinburgh 1, 1953.

This is the latest edition of a book that has become a standard textbook and manual for public health practice in England. The volume covers the knowledge required for the Certificate and Diploma in Public Health under the rules of the General Medical Council. Besides being a valuable compendium of technical knowledge, which has been brought up-to-date by extensive revision, the work is notable for its excellent chapters dealing with administrative and governmental problems of health protection and medical care.

When the previous edition appeared in 1948 the National Health Service Act was so recent that little could be included other than the basic legislation. The intervening years have seen the development of administrative machinery for carrying out the act, modification of the basic law, and passage of the National Assistance Act. Dr. Frazer presents a concise description of these and their effect on public health and medical practice. In an open-minded manner, he intersperses highly objective appraisals, finding both good and bad in the new legislation. The reader who seeks technical information on public hygiene as well as critical factual descriptions of the effect of recent British social legislation on health and medical matters will welcome this new edition.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

QUERIES AND MINOR NOTES

DRUGS TO AVOID IN DIABETICS

TO THE EDITOR:—*It is often stated in medical books and literature that certain commonly used drugs may be used except in diabetics. Please list some of the common drugs and their effects on diabetics.*

R. J. Turner, M.D., Sheridan, Ark.

ANSWER.—Few drugs must be denied to diabetics, but a great many should be used with caution. 1. Elixirs, syrups, and similar preparations with sugar for flavoring are undesirable for a diabetic. 2. Bromides and iodides may lead to pustular eruptions in diabetics, as well as in normal persons. In diabetics, however, any inflammatory lesion is deleterious and lowers the efficacy of insulin. 3. Extracts of the pituitary, thyroid, or adrenals are harmful to diabetics, because they increase the severity of diabetes and counteract the activity of insulin. Epinephrine (Adrenalin) and vasopressin (Pitressin) may be valuable aids in treating insulin hypoglycemia. Cortisone leads to hyperglycemia and glycosuria, but as yet the effects reported have always been temporary. 4. Opium is contraindicated in diabetic coma. Opium so depresses the labored Kussmaul respiration that death in a few moments may follow even a small dose. For this same reason, surgeons avoid the usual doses of morphine before operation on diabetics and are cautious about its use even in small doses. This should be considered particularly when ether is used as an anesthetic, because, through the depressing effect of morphine on the respiration, a larger quantity of ether would be required and ether exerts a toxic action on the glycogen-depleted liver and tends to increase an existing acidosis. Overdosage with tribromoethanol (Avertin), scopolamine, barbiturates, and paraldehyde should be avoided. 5. Iron is contraindicated in hemochromatosis, which so commonly leads to diabetes, and this holds even though anemia appears extreme. 6. Bishydroxycoumarin (Dicumarol) in a diabetic should be used with especial care because of the increased frequency of vascular disease that increases the frequency of hemorrhage in a diabetic. 7. Preparations of salicylic acid are not harmful to the diabetic, but, unless one is alert, the confusing reaction in the urine, when testing for diacetic acid with the ferric chloride test, may be misinterpreted and acidosis wrongly diagnosed. In one such instance, a person was sent home from abroad to avoid diabetic coma because of the confusion resulting from the salicylic acid coating of a pill commonly used for constipation.

TREATMENT OF RHEUMATOID SPONDYLITIS

TO THE EDITOR:—*Please describe the latest treatment for Marie-Strümpell disease.*

O. S. Goodwin, M.D., Apex, N. C.

ANSWER.—The recognized treatment for rheumatoid spondylitis (Marie-Strümpell disease) is roentgen irradiation in conjunction with rest, heat, exercises, and immobilization. This treatment results in lessened pain and stiffness and increased motion in 80% of patients with rheumatoid spondylitis. There is a decrease in the erythrocyte sedimentation rate, but the abnormal roentgen findings remain unaltered and may even increase.

The factors necessary for the roentgen treatment are as follows: 140 kv. with 0.5 mm. of copper, 1 mm. of aluminum filtration, a half value layer of 0.6 mm. copper, 50 cm. skin target distance, and 150 r (measured in air) to each part per treatment, and a total of 600 r for the first course. The ports selected are the sacroiliac (12 by 20 cm.), lumbar spine (20 by 8 cm.), dorsal spine (20 by 8 cm.), and the cervical spine (12 by 20 cm.).

The sacroiliac and the lumbar regions are treated as a unit. The sacroiliac is treated in the morning and the lumbar region in the afternoon daily for four successive days. The dorsal and the cervical regions are treated during the next four days, with one port exposed in the morning and the other port in the afternoon. A second course may be repeated in two months, with the painful sites as ports and 150 r per day given for three successive days, or a total of 450 r. The second course may be repeated if pain persists.

Additional measures are rest in bed with a nonsagging firm mattress until pain, tenderness, and muscle spasm have subsided. The spine should be kept hyperextended to minimize the strain of the spinal ligaments and to obtain optimum chest expansion. This is usually achieved by removing the pillows from under the head. If this procedure fails, a plastic jacket is indicated. Deep breathing exercises are extremely important in order to prevent the costovertebral joint from becoming fixed. Forced deep breathing should be practiced by the patient several times daily for five minute periods. Heat in the form most comforting to the patient should be applied three or four times daily.

VITAMIN B_{12}

TO THE EDITOR:—*Does vitamin B_{12} have any toxic effect when given in doses as large as 1 mg. daily? Is there any indication for the use of massive doses of vitamin B_{12} in paralysis agitans (Parkinson's disease)?*

M.D., Kentucky.

ANSWER.—High potency solutions of vitamin B_{12} for injection have been available for investigational use for two and one-half years and were approved for sale by the Food and Drug Administration in September, 1952. Daily doses of 1,000 μg or more have been administered to numerous patients for periods of several months. To-date, there have been no toxic manifestations or any specific contraindications to its use. In view of the effectiveness of this material in the treatment of macrocytic anemias, the question has frequently been raised as to whether large doses directly affect the hematopoietic system. The weight of research evidence points to vitamin B_{12} as the essential factor in the maturation of erythrocytes and does not indicate that it plays any role in their production. Hematological studies of many patients treated with large doses have failed to show any increase in the total erythrocyte count. There is no published information regarding the use of large doses of vitamin B_{12} in paralysis agitans, and there is nothing in the clinical data thus far accumulated to suggest that it would be of any specific benefit. Certain general effects, such as a sense of well-being, may be expected from its use.

HISTOLOGICAL SECTIONS

TO THE EDITOR:—*A pathologist here delays histological examination of biopsy material as long as seven days. Is there a shorter procedure? Please give details.*

M.D., Dominican Republic.

ANSWER.—If an autotechnicon is used, the tissues can be fixed, dehydrated, and ready for embedding in paraffin in 18 hours. The sections can be cut the day after they are received and stained the next day, then they are ready for diagnosis. Although the period varies, depending on the number of specimens, 48 hours are required, including the typing of reports. If an autotechnicon is not available, the process takes longer. The tissue must be properly fixed, which may take a whole night, depending on the size of the specimen. The tissue is then put in acetone, which is changed every half hour for three changes, then in xylene for 15 minutes, and then in two changes of paraffin, in the first usually for 20 minutes and in

Preparations of salicylic acid are not harmful to the diabetic, but, unless one is alert, the confusing reaction in the urine, when testing for diacetic acid with the ferric chloride test, may be misinterpreted and acidosis wrongly diagnosed. In one such instance, a person was sent home from abroad to avoid diabetic coma because of the confusion resulting from the salicylic acid coating of a pill commonly used for constipation.

TREATMENT OF RHEUMATOID SPONDYLITIS

To the Editor:—*Please describe the latest treatment for Marie-Strümpell disease.*

O. S. Goodwin, M.D., Apex, N. C.

Answer.—The recognized treatment for rheumatoid spondylitis (Marie-Strümpell disease) is roentgen irradiation in conjunction with rest, heat, exercises, and immobilization. This treatment results in lessened pain and stiffness and increased motion in 80% of patients with rheumatoid spondylitis. There is a decrease in the erythrocyte sedimentation rate, but the abnormal roentgen findings remain unaltered and may even increase.

The factors necessary for the roentgen treatment are as follows: 140 kv. with 0.5 mm. of copper, 1 mm. of aluminum filtration, a half value layer of 0.6 mm. copper, 50 cm. skin target distance, and 150 r (measured in air) to each part per treatment, and a total of 600 r for the first course. The ports selected are the sacroiliac (12 by 20 cm.), lumbar spine (20 by 8 cm.), dorsal spine (20 by 8 cm.), and the cervical spine (12 by 20 cm.).

The sacroiliac and the lumbar regions are treated as a unit. The sacroiliac is treated in the morning and the lumbar region in the afternoon daily for four successive days. The dorsal and the cervical regions are treated during the next four days, with one port exposed in the morning and the other port in the afternoon. A second course may be repeated in two months, with the painful sites as ports and 150 r per day given for three successive days, or a total of 450 r. The second course may be repeated if pain persists.

Additional measures are rest in bed with a nonsagging firm mattress until pain, tenderness, and muscle spasm have subsided. The spine should be kept hyperextended to minimize the strain of the spinal ligaments and to obtain optimum chest expansion. This is usually achieved by removing the pillows from under the head. If this procedure fails, a plastic jacket is indicated. Deep breathing exercises are extremely important in order to prevent the costovertebral joint from becoming fixed. Forced deep breathing should be practiced by the patient several times daily for five minute periods. Heat in the form most comforting to the patient should be applied three or four times daily.

VITAMIN B_{12}

To the Editor:—*Does vitamin B_{12} have any toxic effect when given in doses as large as 1 mg. daily? Is there any indication for the use of massive doses of vitamin B_{12} in paralysis agitans (Parkinson's disease)?*

M.D., Kentucky.

Answer.—High potency solutions of vitamin B_{12} for injection have been available for investigational use for two and one-half years and were approved for sale by the Food and Drug Administration in September, 1952. Daily doses of 1,000 µg or more have been administered to numerous patients for periods of several months. To-date, there have been no toxic manifestations or any specific contraindications to its use. In view of the effectiveness of this material in the treatment of macrocytic anemias, the question has frequently been raised as to whether large doses directly affect the hematopoietic system. The weight of research evidence points to vitamin B_{12} as the essential factor in the maturation of erythrocytes and does not indicate that it plays any role in their production. Hematological studies of many patients treated with large doses have failed to show any increase in the total erythrocyte count. There is no published information regarding the use of large doses of vitamin B_{12} in paralysis agitans, and there is nothing in the clinical data thus far accumulated to suggest that it would be of any specific benefit. Certain general effects, such as a sense of well-being, may be expected from its use.

HISTOLOGICAL SECTIONS

To the Editor:—*A pathologist here delays histological examination of biopsy material as long as seven days. Is there a shorter procedure? Please give details.*

M.D., Dominican Republic.

Answer.—If an autotechnicon is used, the tissues can be fixed, dehydrated, and ready for embedding in paraffin in 18 hours. The sections can be cut the day after they are received and stained the next day, then they are ready for diagnosis. Although the period varies, depending on the number of specimens, 48 hours are required, including the typing of reports. If an autotechnicon is not available, the process takes longer. The tissue must be properly fixed, which may take a whole night, depending on the size of the specimen. The tissue is then put in acetone, which is changed every half hour for three changes, then in xylene for 15 minutes, and then in two changes of paraffin, in the first usually for 20 minutes and in

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

the second for one hour. Again, however, the time required depends on the size of the specimen. After the tissue is embedded and cut, the slides can be dried in an oven for several hours, stained, and interpreted the same day.

NODULES IN TENDONS OF HANDS

To the Editor:—*A patient, 52 years of age, has a nodule tendonitis involving the palm of the right hand over the head of the fifth metacarpal bone. An orthopedic surgeon advised that no surgery be done at this time, unless a trigger finger develops. Is x-ray therapy of value in this type of trauma? Leonard B. Fauquier, M.D., Jersey City, N. J.*

Answer.—The occurrence of nodules in the tendons of the hand is fairly common, especially during an attack of chronic rheumatoid arthritis. They are not usually treated surgically, unless a painful trigger finger results. X-ray therapy is often helpful.

REMOVAL OF PERMANGANATE STAINS

To the Editor:—*What will remove potassium permanganate stains from glass urethral syringes?*

Charles H. Codelle, M.D., New York.

Answer.—The brown stains result from manganese oxide deposits formed when potassium permanganate comes in contact with organic matter. They may be removed by soaking of the syringe in a strong mineral acid (sulfuric or hydrochloric) or in a fresh solution of nitrous acid prepared by the addition of sulfuric acid to a nitrite in a cold atmosphere. Care must be exercised to prevent inhalation or exposure of the eyes and skin to the highly toxic fumes. The acid solutions are extremely corrosive and will remove the enamel from graduations on the syringes.

SYSTOLIC "CLICKS"

To the Editor:—*I have observed for the past two years a 35-year-old man who has sharp precordial pain that is unrelated to effort and that lasts less than a second. Electrocardiograms, chest roentgenograms, and results of cardiac examination have always been normal. The only unusual thing has been the presence of a clicking (not split) second heart sound, heard over the precordium but loudest in the mitral area. Please explain the significance of this sound.*

Harold L. Scales, M.D., Teaneck, N. J.

Answer.—The second heart sound is produced by closure of the aortic and pulmonary valves and is, therefore, loudest at the base of the heart. The origin of systolic "clicks" is uncertain but is probably extracardiac. The sounds are often noted in patients with normal hearts. They are always louder at or are confined to the apex and are most clearly heard when the patient is recumbent. The patient in question probably has such an extracardiac sound late in systole, which is loud enough to mask the second sound. This has no pathological significance and cannot be related to the patient's symptom of chest pain.

CEREBRAL COMPLICATIONS OF RUBELLA

To the Editor:—*I have encountered a case of rubella (not rubeola) encephalitis. What is the proper treatment? Is any antibiotic of value?*

K. Clippinger, M.D., Covington, Ohio.

Answer.—There is no specific treatment for the cerebral complications of rubella (German measles). All treatment is symptomatic. Strict bed rest is important throughout the acute stage of the illness. Chloral hydrate, paraldehyde, or intramuscularly administered phenobarbital sodium can be used for the restlessness. The use of opiates should be avoided. If urinary retention or incontinence is present, an indwelling catheter should be employed, with small doses of sulfonamides. Adequate nourishment must be maintained. If the patient is comatose, glucose and amino acids should be given intravenously; if not in deep coma, tube feeding may be employed. Recovery is usually fairly rapid and complete. There are no new drugs or antibiotics that are helpful in this condition.

PENICILLIN REACTIONS

To the Editor:—*Will the addition of an antihistaminic to parenterally administered penicillin control the occurrence of sensitivity reactions due to the penicillin?*

M.D., California.

Answer.—The addition of an antihistaminic drug to penicillin for parenteral administration will not prevent the occurrence of sensitivity reactions. Administration of antihistaminic drugs after the development of skin rashes due to penicillin sensitization will decrease, sometimes markedly, the pruritis that develops, but the other manifestations of the reaction, such as rash or joint pains, fever, and lymphadenopathy in the severer cases are not affected to any appreciable degree by the drug. No other substances are known that will decrease the reactivity to penicillin in patients in whom a sensitivity to this agent has developed. It is important to point out that not all such sensitive persons will react every time they receive penicillin; in some instances, readministration of the drug to a previously sensitive person will not provoke a second allergic reaction. In some patients, not all, sensitivity to penicillin G is not accompanied by allergy to penicillin O; in these cases the latter agent can be given if there is fear of a dangerous reaction to penicillin G. It is possible, however, for patients to become sensitive to penicillin O, and some persons are allergic to both types of the antibiotic.

ASTHMA AND ODORS OF PAINT

To the Editor:—*A man, 30, recently had his first attack of bronchial asthma. He works in a paint and varnish factory as a shipping clerk. There is no history of asthma. He had rheumatic fever at age 11. Physical examination reveals a boggy nasal mucosa and tearing of the eyes. Examination of the heart was within normal limits. The lungs appear normal except during the asthmatic attacks. The blood pressure is 130/70 mm. Hg. A blood cell count revealed eosinophilia, 6%. The patient responded to antiallergic medication, and since he has stopped working his asthma has improved. Could you suggest diagnostic procedures that would aid in establishing the allergen precipitating this patient's bronchial asthma?*

E. Edward Benzier, M.D., Rego Park, N. Y.

Answer.—The odors of paint and varnish frequently incite attacks of asthma. In the majority of such instances they act as irritating vapors that can produce an attack in the presence of a separate allergic factor. Thus they behave like coal smoke, gasoline fumes, and other irritating gases. However, it is also possible that the patient is exposed in his occupation to specific allergy-producing substances. Among such possible causes are linseed products. These allergens as well as others should be employed in testing this patient. The safest procedure would be the scratch test.

SIMULTANEOUS ADMINISTRATION

To the Editor:—*In the Queries and Minor Notes, in "Simultaneous Administration"* (The Journal, *May 16, 1953, page 296), a subscriber raised the question of the safety of administering 5% glucose in sodium chloride and citrated whole blood simultaneously. The answer given was that this procedure was safe provided the solutions were isotonic. I should like to suggest that this answer is incomplete. The effect of exposure of human red blood cells to 5% dextrose is immediate swelling of the cells because of imbibition of water. This can be of sufficient magnitude to cause varying degrees of hemolysis. This effect is more pronounced in stored blood than in fresh blood, since a constant characteristic of refrigerated red blood cells is a decrease in osmotic resistance. The type of procedure mentioned should be reserved for extreme emergencies, since it will undoubtedly lead to varying degrees of intravascular hemolysis of the transfused cells.*

PSYCHIATRIC SERVICES IN GENERAL HOSPITALS

Leslie A. Osborn, M.D., Madison, Wis.

Grouping patients with similar diseases and then separating these groups from each other has long been useful and effective in medical practice. Sometimes these groupings have been made on wards or services of hospitals, and sometimes there have been specialized hospitals. With increased understanding of illness, it has been shown in many instances that the degree of segregation and specialization once thought necessary is no longer required; in fact, coordination and consultation become increasingly difficult if specialization is carried too far. Increasingly we see the development of general hospitals that are organized so that they can treat the full range of human ailments through well-planned construction and organization of services. A good example of the reduced use of specialized hospitals is in the field of infectious disease. Medical knowledge now makes it possible to handle the problems of infectious diseases without risk to others in a general hospital. This same trend is making itself strongly felt in the field of psychiatry.

I have had two kinds of experience as a staff member of general hospitals. Before entering the field of psychiatry, I was an attending physician on the staff of the Charles F. Wilson Memorial Hospital in Johnson City, N. Y., for seven years. For 10 years prior to coming to Wisconsin, I was psychiatrist on the staff of the Edward J. Meyer Memorial Hospital in Buffalo, and, for 5 years, I was in charge of the psychiatric service in that 1,000 bed county general hospital. Since the trend toward development of psychiatric services in general hospitals is increasing and appears to be highly desirable, the following ideas derived from my experience are offered for consideration.

PATIENTS

The greatest increase in persons hospitalized for psychiatric care has been among old persons. The problems of these patients are (*a*) organic changes and (*b*) family and social relationships. The role of the general hospital in this field is unquestioned. The further need is for development of total geriatric programs in which increasing hospitalization can be linked with other services to the aged. This service to older persons does not functionally belong in state hospitals, although patients in that group represent about 50% of the admissions across the country. Care of the aged requires consideration of homes and infirmaries for such persons and provision for care of the chronically ill.

Hospitalization of younger psychiatric patients has not, in my opinion, materially increased. I believe that developments in family life, child care, education, and social opportunity are already reducing the number of very severe personality casualties. Methods of treating those that do occur are improving, so that the old defeatist and custodial concepts of hospitalization are disappearing. With rare exceptions, such patients can be managed, if conditions are appropriate, under general hospital conditions. Such hospital conditions must be functionally designed for the purpose; such is not always the case at the present time in the units that do exist.

TYPES OF DISORDERS

There is a great increase in the number of patients whose personality reactions are not of major dimensions but who are being brought under medical care. These personality reactions occur in diverse forms: frank anxiety phenomena, marked tension, psychosomatic manifestations, acute interpersonal difficulties, and excessive drinking. The presence of specialized hospitals indicates that a sorting-out process has already taken place. The great need in the care of persons with minor disturbances is for a sorting-out process that defines the underlying personal problems and then proceeds to deal with them on their merits. A general hospital is a far more effective place to develop such services than a specialized institution.

Modern psychiatry is essentially the personal aspect of medical practice. Personal, family, and social problems enter into the illnesses and handicaps that are dealt with every day in the general hospital. Reactions of patients to illness and invalidism come within the scope of the physician's responsibility in caring for patients. In this modern sense, psychiatry permeates medical practice and, so, does not lend itself to an arbitrary separation from general medical care.

Medical students in recent years have obtained much more education in personal problems of patients than in years gone by. Many older physicians are self-educated and effective in the field. Others, who find themselves very limited by their meager preparation for this type of work, develop a strong "organic bias" in their clinical approach. Younger physicians, accordingly, are on the alert for personal factors that contribute to patients' symptoms and illnesses, and they do not go to extremes to try to prove an illness is organic before they look into personal and family situations. All diagnosis should be positive, even though some factors of exclusion come into it. Psychiatrically oriented physicians are increasingly able to make positive diagnoses of anxiety problems.

SCOPE AND AIMS

The traditional tendency to approach psychiatry by limiting its benefits to the few extremely sick patients who have been called psychotic is unsound. This is no more workable than was the comparable tendency to limit consideration of tuberculosis to the far advanced condition of the "consumptive." What is required now is a health approach that embodies concern for the health of the personality, interpersonal relationships, and social adjustment as much as for the healthy functioning of the organs and tissues. By such an approach, patients would be examined to see if they are well rather than sick. By recognizing and dealing promptly with a wide variety of personal difficulties, the ultimate development of severer troubles would be prevented.

When dealt with in some ways, a disturbed person can be a very disturbing person. General hospitals tend to assume that any psychiatric service includes noise, risk of physical violence, and extremes of irrational behavior; it is possible to set up conditions and to approach patients in such a way that all these things happen. It is also possible, through a nonfearful, understandingly human approach to patients by all the staff and through the actual physical surroundings, to calm the excitement. Under such conditions there is seldom noise, and overt aggression is rare; the behavior of patients is usually that of insecure people trying to find reassurance.

The clue to development of an effective psychiatric service is primarily in personal attitudes to patients not only on the psychiatric service but throughout the hospital. A coldly impersonal, managed, routine set-up in which the patient must take his place in a veritable hospital production line will have quite a different effect from one that begins with the sick patient and sets up procedures with consideration for the person and his feelings as well as for the technical procedures that may be indicated for diagnosis and treatment.

The aim of a psychiatric service should be to work as openly and freely as possible. If illness takes away a person's capacity to act freely with self-direction, the treatment program should be calculated to restore this capacity. The traditional concept of confinement and locked doors works in the opposite direction; it makes it appear that the physician, rather than the illness, is taking away the patient's freedom. This is like blaming the physician, rather than the illness, when cardiac decompensation prevents a patient from climbing stairs. A combination of good psychiatry and good architecture can produce a service in which patients are so handled that occasion for restraint or confinement is very infrequent. The greater part of psychiatry can and preferably should be carried on in open ward situations. Any use of force, coercion, or confinement should be considered an acknowledgment of therapeutic defeat because of inability to win the free cooperation of the patient.

ARCHITECTURAL DESIGN

The design of hospitals should be functional; changes in treatment require changes in structural arrangements. When surgical patients were kept in bed for one and a half to two weeks after surgery, the bed was the treatment area. With present day ambulatory treatment, patients are frequently out of bed the day after surgery; this requires activity space on surgical wards that was not called for in the past. On psychiatric services in most instances, the time during which the patient is in bed is the least active treatment time. Provisions for sleeping and eating are no more than a background for treatment possibilities. In some hospitals (notably in Montreal), the patients come to the hospital in the morning, take part in the day program, and go home in the evening. Any psychiatric service requires patient activity space and treatment space. Patient activity areas include day rooms, a place for active participation in music, occupational therapy, and recreation, and the opportunity to care for others as a form of altruistic self-expression. Primarily, treatment areas should provide comfortable, acoustically treated interview offices that are not too large and that assure privacy and freedom from interruption. Group meeting rooms may also be used for staff conferences and group therapy. Most psychiatric services lack such facilities. If suitably designed and located, these facilities can serve outpatient as well as inpatient purposes.

ASPECTS OF FUNCTION

Psychiatric service in a general hospital has four aspects of function. First is the structure of the psychiatric ward or service itself. The design should be functional and should provide maximum freedom and a relaxing atmosphere that bespeaks the attitude of the staff and hospital to the patient. It should have facilities for caring for the occasional noisy patient in a soundproof room. Emphasis should be positive and aimed toward attractiveness and relaxing effect rather than negative and concerned chiefly with precaution against destruction and escape. There should be some provision for relative grouping of patients and provision for quiet pursuits, such as reading, and for louder group enterprises. Activities that are creative, such as playing the piano, singing, and painting, should be given preference over passive ones, such as listening to the radio or watching television; while the latter have their place, they should not crowd out the former.

Provision should be made for caring for children, preferably on a small unit primarily designed for them. Maximum self-help by patients should be encouraged; cafeteria meals are preferable to passive food service to patients. Access to the outdoors is desirable. It is questionable whether patients should wear hospital clothing during the daytime. It is doubtful whether segregation of the sexes is necessary. Michael Reese Hospital in Chicago has a new Institute for Psychiatric and Psychosomatic Research in which men and women share day rooms and mingle, even on the ward for disturbed patients. Each room has its own toilet. For disturbed patients each toilet is kept locked but is opened for the patient by the attendant on request. There is considerable social composure and quieting when the sexes are together, as compared with segregation, during the periods of social activity. This arrangement should not be difficult because of the desirability of single rooms in primary construction.

There has probably been a false economy in constructing dormitory facilities; now that many more patients care for themselves in the hospital, the disadvantages of the dormitory are more apparent than ever. Patients like and need privacy. All sorts of interpersonal complications are avoided if each patient has a room of his own. For psychiatric purposes, particularly, a predominance of single units is highly desirable. If patients stay longer, there is need for a small number of two bed units. Probably after the two bed unit, the next most desirable is a five bed unit. This gives some companionship and the beginning of group formation, yet does not provide the risk of leaving one patient out as can happen if three or four persons share accommodations. For any hospital purposes, sleeping units for more than five persons appear highly undesirable.

The second aspect of psychiatric function in the general hospital is provision of liaison service covering principally psychosomatic disturbances. Sometimes the psychological effect of treating such patients on a general medical ward (where of necessity there may be considerable preoccupation with tests, procedures, and medications) can be unsatisfactory. A service that is primarily designed for emphasis on the patient as a person and that considers organic procedures as necessary but unaccented parts of the total investigation may have better therapeutic results. Some interesting psychosomatic correlates emerge, and general practitioners and specialists in other fields find common interests with phychiatrists who are working on the more personal aspects of patients' problems. Rooms suitable for staff conferences and for group therapy have been found increasingly useful in the treatment of pyschosomatic problems.
